op_diagflat *Create a two-dimensional array with the flattened input diagonal.*

Description

the k-th diagonal.

Usage

```
op_diagflat(x, k = 0L)
```

Arguments

x	Input tensor to be flattened and placed on the diagonal.
k	The diagonal to place the flattened input. Defaults to 0. Use k > 0 for diagonals above the main diagonal, and k < 0 for diagonals below the main diagonal.

Value

A 2-D tensor with the flattened input on the specified diagonal.

`op_diagonal` *Return specified diagonals.*

Description

If `x` is 2-D, returns the diagonal of `x` with the given offset, i.e., the collection of elements of the form `x[i, i+offset]`.

If `x` has more than two dimensions, the axes specified by `axis1` and `axis2` are used to determine the 2-D sub-array whose diagonal is returned.

The shape of the resulting array can be determined by removing `axis1` and `axis2` and appending an index to the right equal to the size of the resulting diagonals.

Usage

```
op_diagonal(x, offset = 0L, axis1 = 1L, axis2 = 2L)
```

Arguments

x	Input tensor.
offset	Offset of the diagonal from the main diagonal. Can be positive or negative. Defaults to 0 (main diagonal).
axis1	Axis to be used as the first axis of the 2-D sub-arrays. Defaults to 1 (first axis).
axis2	Axis to be used as the second axis of the 2-D sub-arrays. Defaults to 2 (second axis).

Value

Tensor of diagonals.

Examples

```
x <- op_arange(4L) |> op_reshape(c(2, 2))
x

## tf.Tensor(
## [[1 2]
##  [3 4]], shape=(2, 2), dtype=int32)

op_diagonal(x)

## tf.Tensor([1 4], shape=(2), dtype=int32)

op_diagonal(x, offset = 1)

## tf.Tensor([2], shape=(1), dtype=int32)

x <- op_array(1:8) |> op_reshape(c(2, 2, 2))
x

## tf.Tensor(
## [[[1 2]
##   [3 4]]
##
##  [[5 6]
##   [7 8]]], shape=(2, 2, 2), dtype=int32)
```

```
x |> op_diagonal(0)

## tf.Tensor(
## [[1 7]
##  [2 8]], shape=(2, 2), dtype=int32)

x |> op_diagonal(0, 1, 2) # same as above, the default

## tf.Tensor(
## [[1 7]
##  [2 8]], shape=(2, 2), dtype=int32)

x |> op_diagonal(0, 2, 3)

## tf.Tensor(
## [[1 4]
##  [5 8]], shape=(2, 2), dtype=int32)
```

`op_diff` *Calculate the n-th discrete difference along the given axis.*

Description

The first difference is given by `out[i] = a[i+1] - a[i]` along the given axis, higher differences are calculated by using `diff` recursively.

Usage

```
op_diff(a, n = 1L, axis = -1L)
```

Arguments

`a`	Input tensor.
`n`	The number of times values are differenced. Defaults to `1`.
`axis`	Axis to compute discrete difference(s) along. Defaults to `-1` (last axis).

Value

Tensor of diagonals.

Examples

```
x <- op_array(c(1, 2, 4, 7, 0))
op_diff(x)

## tf.Tensor([ 1.  2.  3. -7.], shape=(4), dtype=float32)
```

```
op_diff(x, n = 2)

## tf.Tensor([  1.   1. -10.], shape=(3), dtype=float32)

x <- op_array(rbind(c(1, 3, 6, 10),
                    c(0, 5, 6, 8)))
op_diff(x)

## tf.Tensor(
## [[2. 3. 4.]
##  [5. 1. 2.]], shape=(2, 3), dtype=float64)

op_diff(x, axis = 1)

## tf.Tensor([[-1.  2.  0. -2.]], shape=(1, 4), dtype=float64)
```

`op_digitize` *Returns the indices of the bins to which each value in* `x` *belongs.*

Description

Returns the indices of the bins to which each value in `x` belongs.

Usage

```
op_digitize(x, bins, zero_indexed = FALSE)
```

Arguments

`x`	Input array to be binned.
`bins`	Array of bins. It has to be one-dimensional and monotonically increasing.
`zero_indexed`	If `TRUE`, the returned indices are zero-based (`0` encodes to first bin); if `FALSE` (default), the returned indices are one-based (`1` encodes the first bin).

Value

Output array of indices, of same shape as `x`.

Examples

```
x <- op_array(c(-1,    0, 1,    3, 3.5,      4.5,  1.6,    8))
bins <- array(c(    0,       3,         4.5,            7))
op_digitize(x, bins)

## tf.Tensor([1 2 2 3 3 4 2 5], shape=(8), dtype=int32)
```

op_divide *Divide arguments element-wise.*

Description

Note that this function is automatically called when using the R operator * with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_divide(x, 2)

## tf.Tensor([0.5 1.  1.5 2. ], shape=(4), dtype=float32)

x / 2

## tf.Tensor([0.5 1.  1.5 2. ], shape=(4), dtype=float32)
```

Usage

```
op_divide(x1, x2)
```

Arguments

x1	First input tensor.
x2	Second input tensor.

Value

Output tensor, the quotient x1/x2, element-wise.

Example

```
op_divide(3, 2)

## tf.Tensor(1.5, shape=(), dtype=float32)
```

`op_divide_no_nan` *Safe element-wise division which returns 0 where the denominator is 0.*

Description

Safe element-wise division which returns 0 where the denominator is 0.

Usage

```
op_divide_no_nan(x1, x2)
```

Arguments

x1	First input tensor.
x2	Second input tensor.

Value

The quotient x1/x2, element-wise, with zero where x2 is zero.

op_dot *Dot product of two tensors.*

Description

- If both x1 and x2 are 1-D tensors, it is inner product of vectors (without complex conjugation).
- If both x1 and x2 are 2-D tensors, it is matrix multiplication.
- If either x1 or x2 is 0-D (scalar), it is equivalent to x1 * x2.
- If x1 is an N-D tensor and x2 is a 1-D tensor, it is a sum product over the last axis of x1 and x2.
- If x1 is an N-D tensor and x2 is an M-D tensor (where M >= 2), it is a sum product over the last axis of x1 and the second-to-last axis of x2: dot(x1, x2)[i,j,k,m] = sum(a[i,j,:] * b[k,:,m]).

Usage

```
op_dot(x1, x2)
```

Arguments

x1	First argument.
x2	Second argument.

Value

Dot product of x1 and x2.

Note

Torch backend does not accept 0-D tensors as arguments.

`op_dot_product_attention`

Scaled dot product attention function.

Description

Computes the attention function on Q (`query`), K (`key`), and V(`value`): `attention(Q, K, V) = softmax(Q * K / sqrt(d)) * V`. If we define `logits` as the output of `Q * K` and the `probs` as the output of `softmax`.

Throughout this function, we utilize the following notation to represent the shape of array:

- B: batch size

- S: length of the key/value
- T: length of the query
- N: number of attention heads
- H: dimensions of each attention head
- K: number of key/value heads
- G: number of groups, which equals to `N // K`

Usage

```
op_dot_product_attention(
  query,
  key,
  value,
  bias = NULL,
  mask = NULL,
  scale = NULL,
  is_causal = FALSE,
  flash_attention = NULL
)
```

Arguments

`query`	The query array with the shape of `(B, T, N, H)`.
`key`	The key array with the shape of `(B, S, K, H)`. When `K` equals `N`, multi-headed attention (MHA) is performed. Otherwise, grouped query attention (GQA) is performed if `N` is a multiple of `K`. and multi-query attention (MQA) is performed if `K==1` (a special case of GQA).
`value`	The value array with the same shape of `key`.
`bias`	Optional bias array to be added to logits. The shape must be broadcastable to `(B, N, T, S)`.
`mask`	Optional mask array used to filter out logits. It is a boolean mask where `TRUE` indicates the element should take part in attention. For an additive mask, users should pass it to bias. The shape must be broadcastable to `(B, N, T, S)`.
`scale`	Optional scale for the logits. If `NULL`, the scale will be set to `1.0 / sqrt(H)`.
`is_causal`	Whether to apply causal mask.
`flash_attention`	Whether to use flash attention. If `NULL`, it will attempt to use flash attention if the required conditions are met. Typically, the inputs must be in float16 and bfloat16 dtype and the input layout requirements may vary depending on the backend.

Value

An array of the attention output with the same shape of `query`.

Examples

```
query = random_normal(c(2, 4, 8, 16))
key = random_normal(c(2, 6, 8, 16))
value = random_normal(c(2, 6, 8, 16))
op_dot_product_attention(query, key, value) |> op_shape()

## shape(2, 4, 8, 16)
```

`op_dtype` *Return the dtype of the tensor input as a standardized string.*

Description

Note that due to the standardization, the dtype will not compare equal to the backend-specific version of the dtype.

Usage

```
op_dtype(x)
```

Arguments

x	A tensor. This function will try to access the `dtype` attribute of the input tensor.

Value

A string indicating the dtype of the input tensor, e.g. `"float32"`.

Examples

```
x <- op_zeros(c(8, 12))
op_dtype(x)
```

```
## [1] "float32"
```

`op_eig` *Computes the eigenvalues and eigenvectors of a square matrix.*

Description

Computes the eigenvalues and eigenvectors of a square matrix.

Usage

```
op_eig(x)
```

Arguments

`x`	Input tensor of shape `(..., M, M)`.

Value

A list of two tensors: a tensor of shape `(..., M)` containing eigenvalues and a tensor of shape `(..., M, M)` containing eigenvectors.

op_einsum *Evaluates the Einstein summation convention on the operands.*

Description

Evaluates the Einstein summation convention on the operands.

Usage

```
op_einsum(subscripts, ...)
```

Arguments

subscripts	Specifies the subscripts for summation as comma separated list of subscript labels. An implicit (classical Einstein summation) calculation is performed unless the explicit indicator -> is included as well as subscript labels of the precise output form.
...	The operands to compute the Einstein sum of.

Value

The calculation based on the Einstein summation convention.

Examples

```
a <- op_arange(25) |> op_reshape(c(5, 5))
b <- op_arange(5)
c <- op_arange(6) |> op_reshape(c(2, 3))
```

Trace of a matrix:

```
op_einsum("ii", a)
op_trace(a)
```

```
## tf.Tensor(65.0, shape=(), dtype=float32)
## tf.Tensor(65.0, shape=(), dtype=float32)
```

Extract the diagonal:

```
op_einsum("ii -> i", a)
op_diag(a)
```

```
## tf.Tensor([ 1.  7. 13. 19. 25.], shape=(5), dtype=float32)
## tf.Tensor([ 1.  7. 13. 19. 25.], shape=(5), dtype=float32)
```

Sum over an axis:

```
op_einsum("ij -> i", a)
op_sum(a, axis = 2)
```

```
## tf.Tensor([ 15.  40.  65.  90. 115.], shape=(5), dtype=float32)
## tf.Tensor([ 15.  40.  65.  90. 115.], shape=(5), dtype=float32)
```

For higher dimensional tensors summing a single axis can be done with ellipsis:

```
op_einsum("...j -> ...", a)
op_sum(a, axis = -1)
```

```
## tf.Tensor([ 15.  40.  65.  90. 115.], shape=(5), dtype=float32)
## tf.Tensor([ 15.  40.  65.  90. 115.], shape=(5), dtype=float32)
```

Compute a matrix transpose or reorder any number of axes:

```
op_einsum("ji", c) # return c unchanged
```

```
## tf.Tensor(
## [[1. 2. 3.]
##  [4. 5. 6.]], shape=(2, 3), dtype=float32)
```

```
op_einsum("ij -> ji", c) # transpose
op_transpose(c)          # same as above
```

```
## tf.Tensor(
## [[1. 4.]
##  [2. 5.]
##  [3. 6.]], shape=(3, 2), dtype=float32)
## tf.Tensor(
## [[1. 4.]
##  [2. 5.]
##  [3. 6.]], shape=(3, 2), dtype=float32)
```

Matrix vector multiplication:

```
op_einsum("ij, j", a, b)
op_einsum("...j, j", a, b)
a %*% b
op_matmul(a, b)
```

```
## tf.Tensor([ 55. 130. 205. 280. 355.], shape=(5), dtype=float32)
## tf.Tensor([ 55. 130. 205. 280. 355.], shape=(5), dtype=float32)
## tf.Tensor([ 55. 130. 205. 280. 355.], shape=(5), dtype=float32)
## tf.Tensor([ 55. 130. 205. 280. 355.], shape=(5), dtype=float32)
```

`op_elu` *Exponential Linear Unit activation function.*

Description

It is defined as:
`f(x) =  alpha * (exp(x) - 1.) for x < 0`, `f(x) = x for x >= 0`.

Usage

```
op_elu(x, alpha = 1)
```

Arguments

x	Input tensor.
alpha	A scalar, slope of positive section. Defaults to `1.0`.

Value

A tensor with the same shape as `x`.

Examples

```
x <- op_array(c(-1., 0., 1.))
op_elu(x)
```

```
## tf.Tensor([-0.63212055  0.          1.        ], shape=(3), dtype=float32)
```

op_empty *Return a tensor of given shape and type filled with uninitialized data.*

Description

Return a tensor of given shape and type filled with uninitialized data.

Usage

```
op_empty(shape, dtype = NULL)
```

Arguments

shape	Shape of the empty tensor.
dtype	Desired data type of the empty tensor.

Value

The empty tensor.

op_equal *Returns* (x1 == x2) *element-wise.*

Description

Note that this function is automatically called when using the R operator == with a tensor.

```
(x <- op_arange(4))
```

```
## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)
```

```
op_equal(x, 2)
```

```
## tf.Tensor([False  True False False], shape=(4), dtype=bool)
```

```
x == 2
```

```
## tf.Tensor([False  True False False], shape=(4), dtype=bool)
```

Usage

```
op_equal(x1, x2)
```

Arguments

x1	Tensor to compare.
x2	Tensor to compare.

Value

Output tensor, element-wise comparison of x1 and x2.

op_erf *Computes the error function of* x*, element-wise.*

Description

Computes the error function of x, element-wise.

Usage

```
op_erf(x)
```

Arguments

x	Input tensor.

Value

A tensor with the same dtype as x.

Examples

```
x <- op_array(c(-3, -2, -1, 0, 1))
op_erf(x)

## tf.Tensor([-0.99997777 -0.9953222  -0.84270084  0.        0.84270084], shape=(5), dtype=float32)

# array([-0.99998 , -0.99532, -0.842701,  0.,  0.842701], dtype=float32)
```

`op_erfinv` *Computes the inverse error function of* `x`*, element-wise.*

Description

Computes the inverse error function of `x`, element-wise.

Usage

```
op_erfinv(x)
```

Arguments

x	Input tensor.

Value

A tensor with the same dtype as `x`.

Examples

```
x <- op_array(c(-0.5, -0.2, -0.1, 0.0, 0.3))
op_erfinv(x)
```

```
## tf.Tensor([-0.4769363  -0.17914344 -0.088856   0.         0.27246267], shape=(5), dtype=float32)
```

op_exp *Calculate the exponential of all elements in the input tensor.*

Description

Calculate the exponential of all elements in the input tensor.

Usage

```
op_exp(x)
```

Arguments

x	Input tensor.

Value

Output tensor, element-wise exponential of `x`.

op_expand_dims *Expand the shape of a tensor.*

Description

Insert a new axis at the `axis` position in the expanded tensor shape.

Usage

```
op_expand_dims(x, axis)
```

Arguments

`x`	Input tensor.
`axis`	Position in the expanded axes where the new axis (or axes) is placed.

Value

Output tensor with the number of dimensions increased.

op_expm1 *Calculate* `exp(x) - 1` *for all elements in the tensor.*

Description

Calculate `exp(x) - 1` for all elements in the tensor.

Usage

```
op_expm1(x)
```

Arguments

x	Input values.

Value

Output tensor, element-wise exponential minus one.

`op_extract_sequences` *Expands the dimension of last axis into sequences of* `sequence_length`.

Description

Slides a window of size `sequence_length` over the last axis of the input with a stride of `sequence_stride`, replacing the last axis with `[num_sequences, sequence_length]` sequences.

If the dimension along the last axis is N, the number of sequences can be computed by:
`num_sequences = 1 + (N - sequence_length) // sequence_stride`

Usage

```
op_extract_sequences(x, sequence_length, sequence_stride)
```

Arguments

`x`	Input tensor.
`sequence_length`	An integer representing the sequences length.
`sequence_stride`	An integer representing the sequences hop size.

Value

A tensor of sequences with shape `[..., num_sequences, sequence_length]`.

Examples

```
x <- op_convert_to_tensor(1:6)
op_extract_sequences(x, 3, 2)

## tf.Tensor(
## [[1 2 3]
##  [3 4 5]], shape=(2, 3), dtype=int32)
```

op_eye *Return a 2-D tensor with ones on the diagonal and zeros elsewhere.*

Description

Return a 2-D tensor with ones on the diagonal and zeros elsewhere.

Usage

```
op_eye(N, M = NULL, k = 0L, dtype = NULL)
```

Arguments

N	Number of rows in the output.
M	Number of columns in the output. If NULL, defaults to N.
k	Index of the diagonal: 0 (the default) refers to the main diagonal, a positive value refers to an upper diagonal, and a negative value to a lower diagonal.
dtype	Data type of the returned tensor.

Value

Tensor with ones on the k-th diagonal and zeros elsewhere.

`op_fft` *Computes the Fast Fourier Transform along last axis of input.*

Description

Computes the Fast Fourier Transform along last axis of input.

Usage

```
op_fft(x)
```

Arguments

`x`	list of the real and imaginary parts of the input tensor. Both tensors provided should be of floating type.

Value

A list containing two tensors - the real and imaginary parts of the output tensor.

Examples

```
x = c(op_array(c(1., 2.)),
      op_array(c(0., 1.)))
op_fft(x)
```

```
## [[1]]
## tf.Tensor([ 3. -1.], shape=(2), dtype=float32)
##
## [[2]]
## tf.Tensor([ 1. -1.], shape=(2), dtype=float32)
```

op_fft2 *Computes the 2D Fast Fourier Transform along the last two axes of input.*

Description

Computes the 2D Fast Fourier Transform along the last two axes of input.

Usage

```
op_fft2(x)
```

Arguments

x	list of the real and imaginary parts of the input tensor. Both tensors provided should be of floating type.

Value

A list containing two tensors - the real and imaginary parts of the output.

Examples

```
x <- c(op_array(rbind(c(1, 2),
                      c(2, 1))),
       op_array(rbind(c(0, 1),
                      c(1, 0))))
op_fft2(x)
```

```
## [[1]]
## tf.Tensor(
## [[ 6.  0.]
##  [ 0. -2.]], shape=(2, 2), dtype=float64)
##
## [[2]]
## tf.Tensor(
## [[ 2.  0.]
##  [ 0. -2.]], shape=(2, 2), dtype=float64)
```

op_flip *Reverse the order of elements in the tensor along the given axis.*

Description

The shape of the tensor is preserved, but the elements are reordered.

Usage

```
op_flip(x, axis = NULL)
```

Arguments

x	Input tensor.
axis	Axis or axes along which to flip the tensor. The default, axis = NULL, will flip over all of the axes of the input tensor.

Value

Output tensor with entries of axis reversed.

`op_floor` *Return the floor of the input, element-wise.*

Description

The floor of the scalar `x` is the largest integer `i`, such that `i <= x`.

Usage

```
op_floor(x)
```

Arguments

`x`	Input tensor.

Value

Output tensor, element-wise floor of `x`.

`op_floor_divide` *Returns the largest integer smaller or equal to the division of inputs.*

Description

Note that this function is automatically called when using the R operator `%/%` with a tensor.

```
(x <- op_arange(10))

## tf.Tensor([ 1.  2.  3.  4.  5.  6.  7.  8.  9. 10.], shape=(10), dtype=float32)

op_floor_divide(x, 2)

## tf.Tensor([0. 1. 1. 2. 2. 3. 3. 4. 4. 5.], shape=(10), dtype=float32)

x %/% 2

## tf.Tensor([0. 1. 1. 2. 2. 3. 3. 4. 4. 5.], shape=(10), dtype=float32)
```

Usage

```
op_floor_divide(x1, x2)
```

Arguments

x1	Numerator.
x2	Denominator.

Value

Output tensor, y <- `floor(x1/x2)`

`op_fori_loop` *For loop implementation.*

Description

For loop implementation.

Usage

```
op_fori_loop(lower, upper, body_fun, init_val)
```

Arguments

`lower`	The initial value of the loop variable.
`upper`	The upper bound of the loop variable.
`body_fun`	A callable that represents the loop body. Must take two arguments: the loop variable and the loop state. The loop state should be updated and returned by this function.
`init_val`	The initial value of the loop state.

Value

The final state after the loop.

Examples

```
lower <- 0L
upper <- 10L
body_fun <- function(i, state) state + i
init_state <- 0L
final_state <- op_fori_loop(lower, upper, body_fun, init_state)
final_state

## tf.Tensor(45, shape=(), dtype=int32)
```

op_full *Return a new tensor of given shape and type, filled with* `fill_value`.

Description

Return a new tensor of given shape and type, filled with `fill_value`.

Usage

```
op_full(shape, fill_value, dtype = NULL)
```

Arguments

`shape`	Shape of the new tensor.
`fill_value`	Fill value.
`dtype`	Desired data type of the tensor.

Value

Output tensor.

`op_full_like` *Return a full tensor with the same shape and type as the given tensor.*

Description

Return a full tensor with the same shape and type as the given tensor.

Usage

```
op_full_like(x, fill_value, dtype = NULL)
```

Arguments

x	Input tensor.
fill_value	Fill value.
dtype	Overrides data type of the result.

Value

Tensor of fill_value with the same shape and type as x.

`op_gelu` *Gaussian Error Linear Unit (GELU) activation function.*

Description

If `approximate` is `TRUE`, it is defined as: `f(x) = 0.5 * x * (1 + tanh(sqrt(2 / pi) * (x + 0.044715 * x^3)))`

Or if `approximate` is `FALSE`, it is defined as: `f(x) = x * P(X <= x) = 0.5 * x * (1 + erf(x / sqrt(2)))`, where `P(X) ~ N(0, 1)`.

Usage

```
op_gelu(x, approximate = TRUE)
```

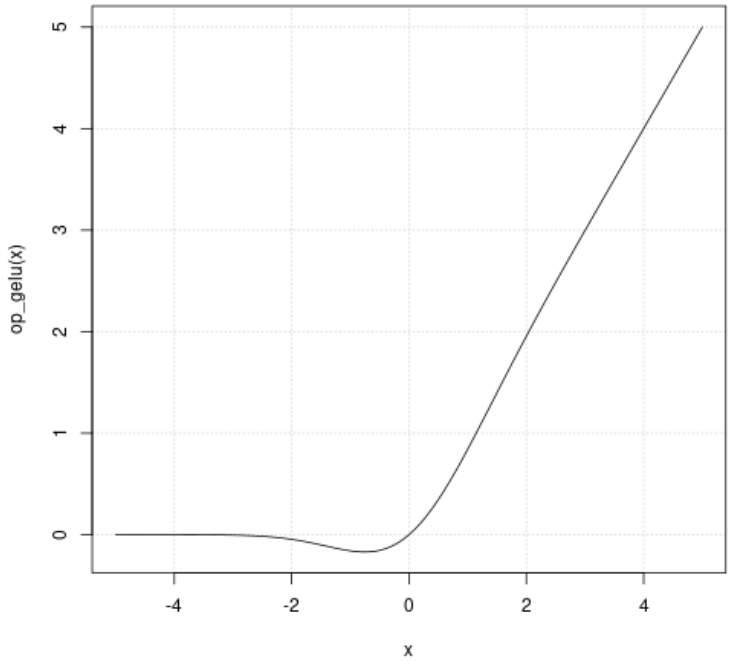
Arguments

`x`	Input tensor.
`approximate`	Approximate version of GELU activation. Defaults to `TRUE`.

Value

A tensor with the same shape as `x`.

Examples



```
x <- op_array(c(-1., 0., 1.))
op_gelu(x)
```

```
## tf.Tensor([-0.15880796  0.          0.841192  ], shape=(3), dtype=float32)
```

```
op_gelu(x, FALSE)
```

```
## tf.Tensor([-0.15865526  0.          0.8413447 ], shape=(3), dtype=float32)
```

```
x <- seq(-5, 5, .1)
plot(x, op_gelu(x),
     type = "l", #, frame.plot = FALSE,
     panel.first = grid())
```

op_get_item *Return* x[key].

Description

Return x[key].

Usage

```
op_get_item(x, key)
```

Arguments

x	A dictionary-like object
key	Generally, a string, but most object with a __hash__ method are acceptable.

Value

key.

Note

Generally, calling x[[key]] or x$key is preferable.

`op_glu` *Gated Linear Unit (GLU) activation function.*

Description

It is defined as:

`f(x) = a * sigmoid(b)` where `x` is split into `a` and `b` along the given axis.

Usage

```
op_glu(x, axis = -1L)
```

Arguments

`x`	Input tensor.
`axis`	The axis along which to split the input tensor. Defaults to `-1`.

Value

A tensor with the same shape as half of the input.

Examples

```
x <- op_array(c(-1., 0., 1. , 1.))
op_glu(x)
```

```
## tf.Tensor([-0.7310586  0.       ], shape=(2), dtype=float32)
```

`op_greater` *Return the truth value of* `x1 > x2` *element-wise.*

Description

Note that this function is automatically called when using the R operator > with a tensor.

```
(x <- op_arange(4))
```

```
## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_greater(x, 2)

## tf.Tensor([False False  True  True], shape=(4), dtype=bool)

x > 2

## tf.Tensor([False False  True  True], shape=(4), dtype=bool)
```

Usage

```
op_greater(x1, x2)
```

Arguments

x1	First input tensor.
x2	Second input tensor.

Value

Output tensor, element-wise comparison of x1 and x2.

`op_greater_equal` *Return the truth value of* `x1 >= x2` *element-wise.*

Description

Note that this function is automatically called when using the R operator >= with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_greater_equal(x, 2)

## tf.Tensor([False  True  True  True], shape=(4), dtype=bool)

x >= 2

## tf.Tensor([False  True  True  True], shape=(4), dtype=bool)
```

Usage

```
op_greater_equal(x1, x2)
```

Arguments

x1	First input tensor.
x2	Second input tensor.

Value

Output tensor, element-wise comparison of x1 and x2.

op_hard_shrink *Hard Shrink activation function.*

Description

The Hard Shrink function is a thresholding operation defined as:

`f(x)` = `x` if `|x| > threshold`, `f(x)` = `0` otherwise.

Usage

```
op_hard_shrink(x, threshold = 0.5)
```

Arguments

`x`	Input tensor.
`threshold`	Threshold value. Defaults to 0.5.

Value

A tensor with the same shape as `x`.

Examples

```
x <- op_array(c(-0.5, 0., 1.))
op_hard_shrink(x)

## tf.Tensor([0. 0. 1.], shape=(3), dtype=float32)
```

`op_hard_sigmoid` *Hard sigmoid activation function.*

Description

It is defined as:
`0 if x < -2.5, 1 if x > 2.5, (0.2 * x) + 0.5 if -2.5 <= x <= 2.5`.

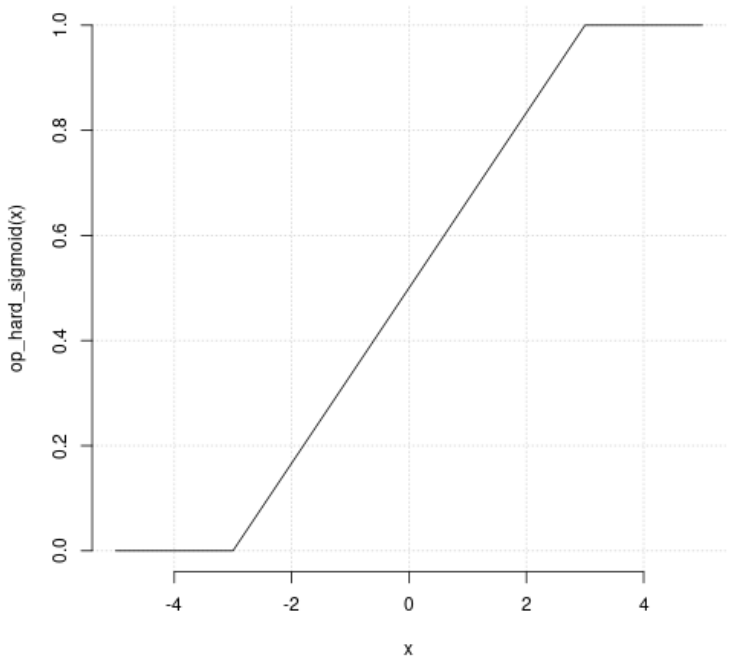
Usage

```
op_hard_sigmoid(x)
```

Arguments

`x`	Input tensor.

Value



A tensor with the same shape as `x`.

Examples

```
x <- op_array(c(-1., 0., 1.))
op_hard_sigmoid(x)
```

```
## tf.Tensor([0.33333334 0.5        0.6666667 ], shape=(3), dtype=float32)
```

```
x <- as.array(seq(-5, 5, .1))
plot(x, op_hard_sigmoid(x),
     type = 'l', panel.first = grid(), frame.plot = FALSE)
```

op_hard_silu *Hard SiLU activation function, also known as Hard Swish.*

Description

It is defined as:

- `0` if `if x < -3`
- `x` if `x > 3`
- `x * (x + 3) / 6` if `-3 <= x <= 3`

It's a faster, piecewise linear approximation of the silu activation.

Usage

```
op_hard_silu(x)

op_hard_swish(x)
```

Arguments

x	Input tensor.

Value

A tensor with the same shape as `x`.

Examples

```
x <- op_convert_to_tensor(c(-3.0, -1.0, 0.0, 1.0, 3.0))
op_hard_silu(x)
```

```
## tf.Tensor([-0.       -0.33333333  0.        0.66666667  3.      ], shape=(5), dtype=float64)
```

`op_hard_tanh` *Applies the HardTanh function element-wise.*

Description

It is defined as:
`f(x) = -1 for x < -1`, `f(x) = x for -1 <= x <= 1`, `f(x) = 1 for x > 1`.

Usage

```
op_hard_tanh(x)
```

Arguments

x	Input tensor.

Value

Output tensor of same shape as `x` where values are clamped between -1 and 1.

Examples

```
x <- op_array(c(-2., -1., 0., 1., 2.))
op_hard_tanh(x)
```

```
## tf.Tensor([-1. -1.  0.  1.  1.], shape=(5), dtype=float32)
```

`op_histogram` *Computes a histogram of the data tensor* `x`.

Description

Computes a histogram of the data tensor `x`.

Usage

```
op_histogram(x, bins = 10L, range = NULL)
```

Arguments

x	Input tensor.
bins	An integer representing the number of histogram bins. Defaults to 10.
range	A pair of numbers representing the lower and upper range of the bins. If not specified, it will use the min and max of x.

Value

A list of two tensors containing:

- A tensor representing the counts of elements in each bin.
- A tensor representing the bin edges.

Examples

```
input_tensor <- random_uniform(8)
c(counts, edges) %<-% op_histogram(input_tensor)

counts

#> tf.Tensor([2. 1. 1. 1. 0. 1. 0. 0. 0. 2.], shape=(10), dtype=float32)

edges

#> tf.Tensor(
#> [0.01647806 0.10867032 0.20086257 0.29305482 0.38524708 0.47743934
#>  0.5696316  0.66182387 0.7540161  0.84620833 0.9384006 ], shape=(11), dtype=float32)
```

`op_hstack` *Stack tensors in sequence horizontally (column wise).*

Description

This is equivalent to concatenation along the first axis for 1-D tensors, and along the second axis for all other tensors.

Usage

```
op_hstack(xs, ...)
```

Arguments

`xs, ...`	list of tensors.

Value

The tensor formed by stacking the given tensors.

`op_identity` *Return the identity tensor.*

Description

The identity tensor is a square tensor with ones on the main diagonal and zeros elsewhere.

Usage

```
op_identity(n, dtype = NULL)
```

Arguments

n	Number of rows (and columns) in the `n x n` output tensor.
dtype	Data type of the output tensor.

Value

The identity tensor.

`op_ifft2` *Computes the 2D Inverse Fast Fourier Transform along the last two axes of*

Description

input.

Usage

```
op_ifft2(x)
```

Arguments

x	Tuple of the real and imaginary parts of the input tensor. Both tensors in the tuple should be of floating type.

Value

A tuple containing two tensors - the real and imaginary parts of the output.

Examples

```
x <- list(op_array(rbind(c(1, 2), c(2, 1))),
          op_array(rbind(c(0, 1), c(1, 0))))
op_ifft2(x)

## [[1]]
## tf.Tensor(
## [[ 1.5  0. ]
##  [ 0.  -0.5]], shape=(2, 2), dtype=float64)
##
## [[2]]
```

```
## tf.Tensor(
## [[ 0.5 -0. ]
##  [-0.  -0.5]], shape=(2, 2), dtype=float64)
```

op_imag *Return the imaginary part of the complex argument.*

Description

Return the imaginary part of the complex argument.

Usage

```
op_imag(x)
```

Arguments

x	Input tensor.

Value

The imaginary component of the complex argument.

`op_image_affine_transform` *Applies the given transform(s) to the image(s).*

Description

Applies the given transform(s) to the image(s).

Usage

```
op_image_affine_transform(
  images,
  transform,
  interpolation = "bilinear",
  fill_mode = "constant",
  fill_value = 0L,
  data_format = NULL
)
```

Arguments

`images`	Input image or batch of images. Must be 3D or 4D.

transform — Projective transform matrix/matrices. A vector of length 8 or tensor of size N x 8. If one row of transform is `[a0, a1, a2, b0, b1, b2, c0, c1]`, then it maps the output point `(x, y)` to a transformed input point `(x', y') = ((a0 x + a1 y + a2) / k, (b0 x + b1 y` where `k = c0 x + c1 y + 1`. The transform is inverted compared to the transform mapping input points to output points. Note that gradients are not backpropagated into transformation parameters. Note that `c0` and `c1` are only effective when using TensorFlow backend and will be considered as `0` when using other backends.

interpolation — Interpolation method. Available methods are `"nearest"`, and `"bilinear"`. Defaults to `"bilinear"`.

fill_mode — Points outside the boundaries of the input are filled according to the given mode. Available methods are `"constant"`, `"nearest"`, `"wrap"` and `"reflect"`. Defaults to `"constant"`.

- `"reflect"`: `(d c b a | a b c d | d c b a)` The input is extended by reflecting about the edge of the last pixel.
- `"constant"`: `(k k k k | a b c d | k k k k)` The input is extended by filling all values beyond the edge with the same constant value k specified by `fill_value`.
- `"wrap"`: `(a b c d | a b c d | a b c d)` The input is extended by wrapping around to the opposite edge.
- `"nearest"`: `(a a a a | a b c d | d d d d)` The input is extended by the nearest pixel.

fill_value — Value used for points outside the boundaries of the input if `fill_mode = "constant"`. Defaults to `0`.

data_format — A string specifying the data format of the input tensor. It can be either `"channels_last"` or `"channels_first"`. `"channels_last"` corresponds to inputs with shape `(batch, height, width, channels)`, while `"channels_first"` corresponds to inputs with shape `(batch, channels, height, width)`.

If not specified, the value will default to `config_image_data_format()`.

Value

Applied affine transform image or batch of images.

Examples

```
x <- random_uniform(c(2, 64, 80, 3)) # batch of 2 RGB images
transform <- op_array(rbind(c(1.5, 0, -20, 0, 1.5, -16, 0, 0),  # zoom
                            c(1, 0, -20, 0, 1, -16, 0, 0)))  # translation))
y <- op_image_affine_transform(x, transform)
shape(y)

## shape(2, 64, 80, 3)

# (2, 64, 80, 3)
```

```
x <- random_uniform(c(64, 80, 3)) # single RGB image
transform <- op_array(c(1.0, 0.5, -20, 0.5, 1.0, -16, 0, 0))  # shear
y <- op_image_affine_transform(x, transform)
shape(y)

## shape(64, 80, 3)

# (64, 80, 3)

x <- random_uniform(c(2, 3, 64, 80)) # batch of 2 RGB images
transform <- op_array(rbind(
  c(1.5, 0,-20, 0, 1.5,-16, 0, 0),  # zoom
  c(1, 0,-20, 0, 1,-16, 0, 0)  # translation
))
y <- op_image_affine_transform(x, transform, data_format = "channels_first")
shape(y)

## shape(2, 3, 64, 80)

# (2, 3, 64, 80)
```

op_image_crop *Crop* images *to a specified* height *and* width.

Description

Crop images to a specified height and width.

Usage

```
op_image_crop(
  images,
  top_cropping = NULL,
```

```
  left_cropping = NULL,
  bottom_cropping = NULL,
  right_cropping = NULL,
  target_height = NULL,
  target_width = NULL,
  data_format = NULL
)
```

Arguments

images	Input image or batch of images. Must be 3D or 4D.
top_cropping	Number of columns to crop from the top.
left_cropping	Number of columns to crop from the left.
bottom_cropping	Number of columns to crop from the bottom.
right_cropping	Number of columns to crop from the right.
target_height	Height of the output images.
target_width	Width of the output images.
data_format	A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to config_image_data_format().

Value

Cropped image or batch of images.

Examples

```
images <- op_reshape(op_arange(1, 28, dtype="float32"), c(3, 3, 3))
images[, , 1] # print the first channel of the images

cropped_images <- op_image_crop(images, 0, 0, 2, 2)
cropped_images[, , 1] # print the first channel of the cropped images
```

op_image_extract_patches *Extracts patches from the image(s).*

Description

Extracts patches from the image(s).

Usage

```
op_image_extract_patches(
  images,
  size,
  strides = NULL,
  dilation_rate = 1L,
  padding = "valid",
  data_format = "channels_last"
)
```

Arguments

images	Input image or batch of images. Must be 3D or 4D.
size	Patch size int or list (patch_height, patch_width)
strides	strides along height and width. If not specified, or if NULL, it defaults to the same value as size.
dilation_rate	This is the input stride, specifying how far two consecutive patch samples are in the input. For value other than 1, strides must be 1. NOTE: strides > 1 is not supported in conjunction with dilation_rate > 1
padding	The type of padding algorithm to use: "same" or "valid".
data_format	A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to config_image_data_format().

Value

Extracted patches 3D (if not batched) or 4D (if batched)

Examples

```
image <- random_uniform(c(2, 20, 20, 3), dtype = "float32") # batch of 2 RGB images
patches <- op_image_extract_patches(image, c(5, 5))
shape(patches)
```

```
## shape(2, 4, 4, 75)

# (2, 4, 4, 75)
image <- random_uniform(c(20, 20, 3), dtype = "float32") # 1 RGB image
patches <- op_image_extract_patches(image, c(3, 3), c(1, 1))
shape(patches)

## shape(18, 18, 27)

# (18, 18, 27)
```

`op_image_gaussian_blur` *Applies a Gaussian blur to the image(s).*

Description

Applies a Gaussian blur to the image(s).

Usage

```
op_image_gaussian_blur(
  images,
  kernel_size = list(3L, 3L),
  sigma = list(1, 1),
  data_format = NULL
)
```

Arguments

`images`	Input image or batch of images. Must be 3D or 4D.
`kernel_size`	A tuple of two integers, specifying the height and width of the Gaussian kernel.

sigma	A tuple of two floats, specifying the standard deviation of the Gaussian kernel along height and width.
data_format	A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to keras.config.image_data_format.

Value

Blurred image or batch of images.

Examples

```
x <- op_ones(c(2, 64, 80, 3))  # batch of 2 RGB images
y <- op_image_gaussian_blur(x)
op_shape(y)

## shape(2, 64, 80, 3)

x <- op_ones(c(64, 80, 3))  # single RGB image
y <- op_image_gaussian_blur(x)
op_shape(y)

## shape(64, 80, 3)

x <- op_ones(c(2, 3, 64, 80))  # batch of 2 RGB images, channels_first
y <- op_image_gaussian_blur(x, data_format = "channels_first")
op_shape(y)

## shape(2, 3, 64, 80)
```

op_image_hsv_to_rgb *Convert HSV images to RGB.*

Description

images must be of float dtype, and the output is only well defined if the values in images are in [0, 1].

Usage

```
op_image_hsv_to_rgb(images, data_format = NULL)
```

Arguments

images	Input image or batch of images. Must be 3D or 4D.
data_format	A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to config_image_data_format().

Value

RGB image or batch of RGB images.

Examples

```
x <- random_uniform(c(2, 4, 4, 3))
y <- op_image_hsv_to_rgb(x)
shape(y)

## shape(2, 4, 4, 3)

x <- random_uniform(c(4, 4, 3)) # Single HSV image
y <- op_image_hsv_to_rgb(x)
shape(y)

## shape(4, 4, 3)

x <- random_uniform(c(2, 3, 4, 4))
y <- op_image_hsv_to_rgb(x, data_format="channels_first")
shape(y)

## shape(2, 3, 4, 4)
```

`op_image_map_coordinates` *Map the input array to new coordinates by interpolation.*

Description

Note that interpolation near boundaries differs from the scipy function, because we fixed an outstanding bug scipy/issues/2640.

Usage

```
op_image_map_coordinates(
  inputs,
  coordinates,
  order,
  fill_mode = "constant",
  fill_value = 0L
)
```

Arguments

`inputs`	The input array.
`coordinates`	The coordinates at which `inputs` is evaluated.
`order`	The order of the spline interpolation. The order must be `0` or `1`. `0` indicates the nearest neighbor and `1` indicates the linear interpolation.
`fill_mode`	Points outside the boundaries of the inputs are filled according to the given mode. Available methods are `"constant"`, `"nearest"`, `"wrap"` and `"mirror"` and `"reflect"`. Defaults to `"constant"`. • `"constant"`: `(k k k k | a b c d | k k k k)` inputs is extended by filling all values beyond the edge with the same constant value k specified by `fill_value`. • `"nearest"`: `(a a a a | a b c d | d d d d)` inputs is extended by the nearest pixel. • `"wrap"`: `(a b c d | a b c d | a b c d)` inputs is extended by wrapping around to the opposite edge.

- "mirror": (c d c b | a b c d | c b a b) inputs is extended by mirroring about the edge.
- "reflect": (d c b a | a b c d | d c b a) inputs is extended by reflecting about the edge of the last pixel.

fill_value Value used for points outside the boundaries of the inputs if fill_mode = "constant". Defaults to 0.

Value

Output input or batch of inputs.

op_image_pad *Pad* images *with zeros to the specified* height *and* width.

Description

Pad images with zeros to the specified height and width.

Usage

```
op_image_pad(
  images,
  top_padding = NULL,
  left_padding = NULL,
  bottom_padding = NULL,
  right_padding = NULL,
  target_height = NULL,
  target_width = NULL,
  data_format = NULL
)
```

Arguments

images	Input image or batch of images. Must be 3D or 4D.
top_padding	Number of rows of zeros to add on top.
left_padding	Number of columns of zeros to add on the left.

bottom_padding	Number of rows of zeros to add at the bottom.
right_padding	Number of columns of zeros to add on the right.
target_height	Height of output images.
target_width	Width of output images.
data_format	A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to config_image_data_format().

Value

Padded image or batch of images.

Examples

```
images <- random_uniform(c(15, 25, 3))
padded_images <- op_image_pad(
    images, 2, 3, target_height = 20, target_width = 30
)
shape(padded_images)

## shape(20, 30, 3)

batch_images <- random_uniform(c(2, 15, 25, 3))
padded_batch <- op_image_pad(batch_images, 2, 3,
                             target_height = 20,
                             target_width = 30)
shape(padded_batch)

## shape(2, 20, 30, 3)
```

`op_image_perspective_transform`
Applies a perspective transformation to the image(s).

Description

Applies a perspective transformation to the image(s).

Usage

```
op_image_perspective_transform(
  images,
  start_points,
  end_points,
  interpolation = "bilinear",
  fill_value = 0L,
  data_format = NULL
)
```

Arguments

`images`	Input image or batch of images. Must be 3D or 4D.
`start_points`	A tensor of shape `(N, 4, 2)` or `(4, 2)`, representing the source points in the original image that define the transformation.
`end_points`	A tensor of shape `(N, 4, 2)` or `(4, 2)`, representing the target points in the output image after transformation.
`interpolation`	Interpolation method. Available methods are `"nearest"`, and `"bilinear"`. Defaults to `"bilinear"`.
`fill_value`	Value used for points outside the boundaries of the input if extrapolation is needed. Defaults to `0`.
`data_format`	A string specifying the data format of the input tensor. It can be either `"channels_last"` or `"channels_first"`. `"channels_last"` corresponds to inputs with shape `(batch, height, width, channels)`, while `"channels_first"` corresponds to inputs with shape `(batch, channels, height, width)`. If not specified, the value will default to `keras.config.image_data_format`.

Value

Applied perspective transform image or batch of images.

Examples

```
# Batch of 2 RGB images (channels_last)
x <- op_ones(c(2, 64, 80, 3))
start_points <- op_stack(list(
  rbind(c(0, 0), c(0, 64), c(80, 0), c(80, 64)),
  rbind(c(0, 0), c(0, 64), c(80, 0), c(80, 64))
```

```
))
end_points <- op_stack(list(
  rbind(c(3, 5), c(7, 64), c(76, -10), c(84, 61)),
  rbind(c(8, 10), c(10, 61), c(65, 3), c(88, 43))
))
y <- op_image_perspective_transform(x, start_points, end_points)
op_shape(y)

## shape(2, 64, 80, 3)

# Single RGB image (channels_last)
x <- op_ones(c(64, 80, 3))
start_points <- rbind(c(0, 0), c(0, 64), c(80, 0), c(80, 64))
end_points <- rbind(c(3, 5), c(7, 64), c(76, -10), c(84, 61))
y <- op_image_perspective_transform(x, start_points, end_points)
op_shape(y)

## shape(64, 80, 3)

# Batch of 2 RGB images (channels_first)
x <- op_ones(c(2, 3, 64, 80))

op_image_resize *Resize images to size using the specified interpolation method.*

Description

Resize images to size using the specified interpolation method.

Usage

```
op_image_resize(
  images,
  size,
  interpolation = "bilinear",
  antialias = FALSE,
  crop_to_aspect_ratio = FALSE,
  pad_to_aspect_ratio = FALSE,
  fill_mode = "constant",
  fill_value = 0,
  data_format = NULL
)
```

Arguments

images	Input image or batch of images. Must be 3D or 4D.
size	Size of output image in (height, width) format.
interpolation	Interpolation method. Available methods are "nearest", "bilinear", and "bicubic". Defaults to "bilinear".
antialias	Whether to use an antialiasing filter when downsampling an image. Defaults to FALSE.
crop_to_aspect_ratio	If TRUE, resize the images without aspect ratio distortion. When the original aspect ratio differs from the target aspect ratio, the output image will be cropped so as to return the largest possible window in the image (of size (height, width)) that matches the target aspect ratio. By default (crop_to_aspect_ratio=FALSE), aspect ratio may not be preserved.
pad_to_aspect_ratio	If TRUE, pad the images without aspect ratio distortion. When the original aspect ratio differs from the target aspect ratio, the output image will be evenly padded on the short side.
fill_mode	When using pad_to_aspect_ratio=TRUE, padded areas are filled according to the given mode. Only "constant" is supported at this time (fill with constant value, equal to fill_value).

fill_value	Float. Padding value to use when pad_to_aspect_ratio=TRUE.
data_format	A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to config_image_data_format().

Value

Resized image or batch of images.

Examples

```
x <- random_uniform(c(2, 4, 4, 3)) # batch of 2 RGB images
y <- op_image_resize(x, c(2, 2))
shape(y)

## shape(2, 2, 2, 3)

x <- random_uniform(c(4, 4, 3)) # single RGB image
y <- op_image_resize(x, c(2, 2))
shape(y)

## shape(2, 2, 3)

x <- random_uniform(c(2, 3, 4, 4)) # batch of 2 RGB images
y <- op_image_resize(x, c(2, 2), data_format = "channels_first")
shape(y)

## shape(2, 3, 2, 2)
```

`op_image_rgb_to_grayscale` *Convert RGB images to grayscale.*

Description

This function converts RGB images to grayscale images. It supports both 3D and 4D tensors, where the last dimension represents channels.

Usage

```
op_image_rgb_to_grayscale(images, data_format = NULL)
```

Arguments

`images`	Input image or batch of images. Must be 3D or 4D.
`data_format`	A string specifying the data format of the input tensor. It can be either `"channels_last"` or `"channels_first"`. `"channels_last"` corresponds to inputs with shape `(batch, height, width, channels)`, while `"channels_first"` corresponds to inputs with shape `(batch, channels, height, width)`. If not specified, the value will default to `config_image_data_format()`.

Value

Grayscale image or batch of grayscale images.

Examples

```
x <- random_uniform(c(2, 4, 4, 3))
y <- op_image_rgb_to_grayscale(x)
shape(y)

## shape(2, 4, 4, 1)

x <- random_uniform(c(4, 4, 3)) # Single RGB image
y = op_image_rgb_to_grayscale(x)
shape(y)

## shape(4, 4, 1)

x <- random_uniform(c(2, 3, 4, 4))
y <- op_image_rgb_to_grayscale(x, data_format="channels_first")
shape(y)

## shape(2, 1, 4, 4)
```

op_image_rgb_to_hsv *Convert RGB images to HSV.*

Description

images must be of float dtype, and the output is only well defined if the values in images are in [0, 1].

All HSV values are in [0, 1]. A hue of 0 corresponds to pure red, 1/3 is pure green, and 2/3 is pure blue.

Usage

```
op_image_rgb_to_hsv(images, data_format = NULL)
```

Arguments

images	Input image or batch of images. Must be 3D or 4D.
data_format	A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to config_image_data_format().

Value

HSV image or batch of HSV images.

Examples

```
x <- random_uniform(c(2, 4, 4, 3))
y <- op_image_rgb_to_hsv(x)
shape(y)

## shape(2, 4, 4, 3)
```

```
x <- random_uniform(c(4, 4, 3)) # Single RGB image
y <- op_image_rgb_to_hsv(x)
shape(y)

## shape(4, 4, 3)

x <- random_uniform(c(2, 3, 4, 4))
y <- op_image_rgb_to_hsv(x, data_format = "channels_first")
shape(y)

## shape(2, 3, 4, 4)
```

`op_inner` *Return the inner product of two tensors.*

Description

Ordinary inner product of vectors for 1-D tensors (without complex conjugation), in higher dimensions a sum product over the last axes.

Multidimensional arrays are treated as vectors by flattening all but their last axes. The resulting dot product is performed over their last axes.

Usage

```
op_inner(x1, x2)
```

Arguments

`x1`	First input tensor.
`x2`	Second input tensor. The last dimension of `x1` and `x2` must match.

Value

Output tensor. The shape of the output is determined by broadcasting the shapes of `x1` and `x2` after removing their last axes.

op_inv *Computes the inverse of a square tensor.*

Description

Computes the inverse of a square tensor.

Usage

```
op_inv(x)
```

Arguments

x	Input tensor of shape (..., M, M).

Value

A tensor of shape (..., M, M) representing the inverse of x.

op_in_top_k *Checks if the targets are in the top-k predictions.*

Description

Checks if the targets are in the top-k predictions.

Usage

```
op_in_top_k(targets, predictions, k)
```

Arguments

targets	A tensor of true labels.
predictions	A tensor of predicted labels.
k	An integer representing the number of predictions to consider.

Value

A boolean tensor of the same shape as `targets`, where each element indicates whether the corresponding target is in the top-k predictions.

Examples

```
targets <- op_array(c(2, 5, 3), "int32")
predictions <- op_array(dtype = "float32", rbind(
  c(0.1, 0.4, 0.6, 0.9, 0.5),
  c(0.1, 0.7, 0.9, 0.8, 0.3),
  c(0.1, 0.6, 0.9, 0.9, 0.5)
))
op_in_top_k(targets, predictions, k = 3L)

## tf.Tensor([ True False  True], shape=(3), dtype=bool)
```

op_irfft *Inverse real-valued Fast Fourier transform along the last axis.*

Description

Computes the inverse 1D Discrete Fourier Transform of a real-valued signal over the inner-most dimension of input.

The inner-most dimension of the input is assumed to be the result of RFFT: the `fft_length / 2 + 1` unique components of the DFT of a real-valued signal. If `fft_length` is not provided, it is computed from the size of the inner-most dimension of the input (`fft_length = 2 * (inner - 1)`). If the FFT length used to compute is odd, it should be provided since it cannot be inferred properly.

Along the axis IRFFT is computed on, if `fft_length / 2 + 1` is smaller than the corresponding dimension of the input, the dimension is cropped. If it is larger, the dimension is padded with zeros.

Usage

```
op_irfft(x, fft_length = NULL)
```

Arguments

`x`	List of the real and imaginary parts of the input tensor. Both tensors in the list should be of floating type.
`fft_length`	An integer representing the number of the fft length. If not specified, it is inferred from the length of the last axis of `x`. Defaults to `NULL`.

Value

A tensor containing the inverse real-valued Fast Fourier Transform along the last axis of `x`.

Examples

```
real <- op_array(c(0, 1, 2, 3, 4))
imag <- op_array(c(0, 1, 2, 3, 4))
op_irfft(c(real, imag))
```

```
#> tf.Tensor(
#> [ 2.         -2.0606601   0.5        -0.35355338  0.          0.06066012
#>  -0.5         0.35355338], shape=(8), dtype=float32)
```

```
all.equal(op_irfft(op_rfft(real, 5), 5), real)
```

```
#> [1] TRUE
```

`op_isclose` *Return whether two tensors are element-wise almost equal.*

Description

Return whether two tensors are element-wise almost equal.

Usage

```
op_isclose(x1, x2, rtol = 1e-05, atol = 1e-08, equal_nan = FALSE)
```

Arguments

`x1`	First input tensor.
`x2`	Second input tensor.
`rtol`	Relative tolerance.
`atol`	Absolute tolerance.
`equal_nan`	If `TRUE`, element-wise `NaN`s are considered equal.

Value

Output boolean tensor.

`op_isfinite` *Return whether a tensor is finite, element-wise.*

Description

Real values are finite when they are not NaN, not positive infinity, and not negative infinity. Complex values are finite when both their real and imaginary parts are finite.

Usage

```
op_isfinite(x)
```

Arguments

x	Input tensor.

Value

Output boolean tensor.

`op_isnan` *Test element-wise for NaN and return result as a boolean tensor.*

Description

Test element-wise for NaN and return result as a boolean tensor.

Usage

```
op_isnan(x)
```

Arguments

x	Input tensor.

Value

Output boolean tensor.

`op_istft` *Inverse Short-Time Fourier Transform along the last axis of the input.*

Description

To reconstruct an original waveform, the parameters should be the same in `stft`.

Usage

```
op_istft(
  x,
  sequence_length,
  sequence_stride,
  fft_length,
  length = NULL,
  window = "hann",
```

```
  center = TRUE
)
```

Arguments

x	Tuple of the real and imaginary parts of the input tensor. Both tensors in the list should be of floating type.
sequence_length	An integer representing the sequence length.
sequence_stride	An integer representing the sequence hop size.
fft_length	An integer representing the size of the FFT that produced stft. Should be of type int32.
length	An integer representing the output is clipped to exactly length. If not specified, no padding or clipping take place. Defaults to NULL.
window	A string, a tensor of the window or NULL. If window is a string, available values are "hann" and "hamming". If window is a tensor, it will be used directly as the window and its length must be sequence_length. If window is NULL, no windowing is used. Defaults to "hann".
center	Whether x was padded on both sides so that the t-th sequence is centered at time t * sequence_stride. Defaults to TRUE.

Value

A tensor containing the inverse Short-Time Fourier Transform along the last axis of x.

Examples

```
x <- op_convert_to_tensor(c(0, 1, 2, 3, 4))
op_istft(op_stft(x, 1, 1, 1), 1, 1, 1)

## tf.Tensor([], shape=(0), dtype=float64)

# array([0.0, 1.0, 2.0, 3.0, 4.0])
```

`op_is_tensor` *Check whether the given object is a tensor.*

Description

Check whether the given object is a tensor.

Usage

```
op_is_tensor(x)
```

Arguments

x	A variable.

Value

TRUE if x is a tensor, otherwise FALSE.

Note

This checks for backend specific tensors so passing a TensorFlow tensor would return FALSE if your backend is PyTorch or JAX.

`op_leaky_relu` *Leaky version of a Rectified Linear Unit activation function.*

Description

It allows a small gradient when the unit is not active, it is defined as:
`f(x) = alpha * x for x < 0` or `f(x) = x for x >= 0`.

Usage

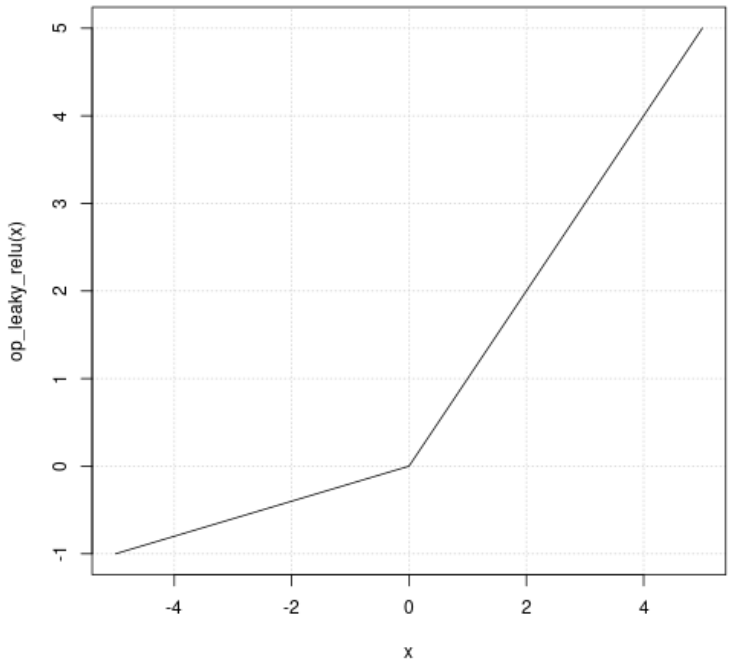
```
op_leaky_relu(x, negative_slope = 0.2)
```

Arguments

`x`	Input tensor.
`negative_slope`	Slope of the activation function at x < 0. Defaults to `0.2`.

Value

A tensor with the same shape as `x`.



Examples

```
x <- op_array(c(-1., 0., 1.))
op_leaky_relu(x)

## tf.Tensor([-0.2  0.   1. ], shape=(3), dtype=float32)

# array([-0.2,  0. ,  1. ], shape=(3,), dtype=float64)

x <- seq(-5, 5, .1)
plot(x, op_leaky_relu(x),
     type = 'l', panel.first = grid())
```

`op_left_shift` *Shift the bits of an integer to the left.*

Description

Bits are shifted to the left by appending `y` 0s at the right of `x`. Since the internal representation of numbers is in binary format, this operation is equivalent to multiplying `x` by `2^y`.

Usage

```
op_left_shift(x, y)
```

Arguments

`x`	Input integer tensor.
`y`	Input integer tensor.

Value

Result tensor.

`op_less` *Return the truth value of* `x1 < x2` *element-wise.*

Description

Note that this function is automatically called when using the R operator < with a tensor.

```
(x <- op_arange(4))
```

```
## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_less(x, 2)

## tf.Tensor([ True False False False], shape=(4), dtype=bool)

x < 2

## tf.Tensor([ True False False False], shape=(4), dtype=bool)
```

Usage

```
op_less(x1, x2)
```

Arguments

x1	First input tensor.
x2	Second input tensor.

Value

Output tensor, element-wise comparison of x1 and x2.

`op_less_equal` *Return the truth value of* `x1 <= x2` *element-wise.*

Description

Note that this function is automatically called when using the R operator <= with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_less_equal(x, 2)

## tf.Tensor([ True  True False False], shape=(4), dtype=bool)

x <= 2

## tf.Tensor([ True  True False False], shape=(4), dtype=bool)
```

Usage

```
op_less_equal(x1, x2)
```

Arguments

x1	First input tensor.
x2	Second input tensor.

Value

Output tensor, element-wise comparison of x1 and x2.

`op_linspace` *Return evenly spaced numbers over a specified interval.*

Description

Returns `num` evenly spaced samples, calculated over the interval `[start, stop]`.

The endpoint of the interval can optionally be excluded.

Usage

```
op_linspace(
  start,
  stop,
  num = 50L,
  endpoint = TRUE,
  retstep = FALSE,
  dtype = NULL,
  axis = 1L
)
```

Arguments

`start`	The starting value of the sequence.
`stop`	The end value of the sequence, unless `endpoint` is set to `FALSE`. In that case, the sequence consists of all but the last of `num + 1` evenly spaced samples, so that `stop` is excluded. Note that the step size changes when `endpoint` is `FALSE`.
`num`	Number of samples to generate. Defaults to `50`. Must be non-negative.
`endpoint`	If `TRUE`, `stop` is the last sample. Otherwise, it is not included. Defaults to `TRUE`.
`retstep`	If `TRUE`, return `(samples, step)`, where `step` is the spacing between samples.
`dtype`	The type of the output tensor.
`axis`	The axis in the result to store the samples. Relevant only if start or stop are array-like. Defaults to `1`, the first axis.

Value

A tensor of evenly spaced numbers. If `retstep` is `TRUE`, returns `(samples, step)`

Note

Torch backend does not support `axis` argument.

`op_log` *Natural logarithm, element-wise.*

Description

Natural logarithm, element-wise.

Usage

```
op_log(x)
```

Arguments

x	Input tensor.

Value

Output tensor, element-wise natural logarithm of `x`.

`op_log10` *Return the base 10 logarithm of the input tensor, element-wise.*

Description

Return the base 10 logarithm of the input tensor, element-wise.

Usage

```
op_log10(x)
```

Arguments

x	Input tensor.

Value

Output tensor, element-wise base 10 logarithm of `x`.

`op_log1p` *Returns the natural logarithm of one plus the* `x`*, element-wise.*

Description

Calculates `log(1 + x)`.

Usage

```
op_log1p(x)
```

Arguments

x	Input tensor.

Value

Output tensor, element-wise natural logarithm of 1 + x.

op_log2 *Base-2 logarithm of* x*, element-wise.*

Description

Base-2 logarithm of x, element-wise.

Usage

```
op_log2(x)
```

Arguments

x	Input tensor.

Value

Output tensor, element-wise base-2 logarithm of x.

`op_logaddexp` *Logarithm of the sum of exponentiations of the inputs.*

Description

Calculates `log(exp(x1) + exp(x2))`.

Usage

```
op_logaddexp(x1, x2)
```

Arguments

`x1`	Input tensor.
`x2`	Input tensor.

Value

Output tensor, element-wise logarithm of the sum of exponentiations of the inputs.

op_logdet *Computes log of the determinant of a hermitian positive definite matrix.*

Description

Computes log of the determinant of a hermitian positive definite matrix.

Usage

```
op_logdet(x)
```

Arguments

x	Input matrix. It must 2D and square.

Value

The natural log of the determinant of matrix.

`op_logical_and` *Computes the element-wise logical AND of the given input tensors.*

Description

Zeros are treated as `FALSE` and non-zeros are treated as `TRUE`.

Usage

```
op_logical_and(x1, x2)
```

Arguments

`x1`	Input tensor.
`x2`	Input tensor.

Details

Note that this function is automatically called when using the R operator `&` with a tensor.

Value

Output tensor, element-wise logical AND of the inputs.

op_logical_or *Computes the element-wise logical OR of the given input tensors.*

Description

Zeros are treated as FALSE and non-zeros are treated as TRUE.

Note that this function is automatically called when using the R operator | with a tensor.

Usage

```
op_logical_or(x1, x2)
```

Arguments

x1	Input tensor.
x2	Input tensor.

Value

Output tensor, element-wise logical OR of the inputs.

`op_logical_xor` *Compute the truth value of* `x1 XOR x2`*, element-wise.*

Description

Compute the truth value of `x1 XOR x2`, element-wise.

Usage

```
op_logical_xor(x1, x2)
```

Arguments

`x1`	First input tensor.
`x2`	Second input tensor.

Value

Output boolean tensor.

`op_logspace` *Returns numbers spaced evenly on a log scale.*

Description

In linear space, the sequence starts at `base ** start` and ends with `base ** stop` (see `endpoint` below).

Usage

```
op_logspace(
  start,
  stop,
  num = 50L,
  endpoint = TRUE,
  base = 10L,
  dtype = NULL,
  axis = 1L
)
```

Arguments

`start`	The starting value of the sequence.
`stop`	The final value of the sequence, unless `endpoint` is `FALSE`. In that case, `num + 1` values are spaced over the interval in log-space, of which all but the last (a sequence of length `num`) are returned.
`num`	Number of samples to generate. Defaults to `50`.
`endpoint`	If `TRUE`, `stop` is the last sample. Otherwise, it is not included. Defaults to `TRUE`.
`base`	The base of the log space. Defaults to `10`.
`dtype`	The type of the output tensor.
`axis`	The axis in the result to store the samples. Relevant only if start or stop are array-like.

Value

A tensor of evenly spaced samples on a log scale.

Note

Torch backend does not support `axis` argument.

`op_logsumexp` *Computes the logarithm of sum of exponentials of elements in a tensor.*

Description

Computes the logarithm of sum of exponentials of elements in a tensor.

Usage

```
op_logsumexp(x, axis = NULL, keepdims = FALSE)
```

Arguments

x	Input tensor.
axis	An integer or a list of integers specifying the axis/axes along which to compute the sum. If NULL, the sum is computed over all elements. Defaults to NULL.
keepdims	A boolean indicating whether to keep the dimensions of the input tensor when computing the sum. Defaults to FALSE.

Value

A tensor containing the logarithm of the sum of exponentials of elements in x.

Examples

```
x <- op_convert_to_tensor(c(1, 2, 3))
op_logsumexp(x)

## tf.Tensor(3.4076059644443806, shape=(), dtype=float64)
```

`op_log_sigmoid` *Logarithm of the sigmoid activation function.*

Description

It is defined as `f(x) = log(1 / (1 + exp(-x)))`.

Usage

```
op_log_sigmoid(x)
```

Arguments

`x`	Input tensor.

Value

A tensor with the same shape as `x`.

Examples

```
x <- op_convert_to_tensor(c(-0.541391, 0.0, 0.50, 5.0))
op_log_sigmoid(x)

## tf.Tensor([-1.00004181 -0.69314718 -0.47407698 -0.00671535], shape=(4), dtype=float64)
```

`op_log_softmax` *Log-softmax activation function.*

Description

It is defined as: `f(x) = x - max(x) - log(sum(exp(x - max(x))))`

Usage

```
op_log_softmax(x, axis = -1L)
```

Arguments

`x`	Input tensor.
`axis`	Integer, axis along which the log-softmax is applied. Defaults to `-1`.

Value

A tensor with the same shape as `x`.

Examples

```
x <- op_array(c(-1., 0., 1.))
op_log_softmax(x)

## tf.Tensor([-2.407606   -1.4076059  -0.40760595], shape=(3), dtype=float32)
```

`op_lstsq` *Return the least-squares solution to a linear matrix equation.*

Description

Computes the vector x that approximately solves the equation `a %*% x = b`. The equation may be under-, well-, or over-determined (i.e., the number of linearly independent rows of a can be less than, equal to, or greater than its number of linearly independent columns). If a is square and of full rank, then x (but for round-off error) is the exact solution of the equation. Else, x minimizes the L2 norm of `b - a %*% x`.

If there are multiple minimizing solutions, the one with the smallest L2 norm is returned.

Usage

```
op_lstsq(a, b, rcond = NULL)
```

Arguments

a	"Coefficient" matrix of shape (M, N).
b	Ordinate or "dependent variable" values, of shape (M) or (M, K). If b is two-dimensional, the least-squares solution is calculated for each of the K columns of b.
rcond	Cut-off ratio for small singular values of a. For the purposes of rank determination, singular values are treated as zero if they are smaller than rcond times the largest singular value of a.

Value

Tensor with shape (N) or (N, K) containing the least-squares solutions.

NOTE: The output differs from numpy.linalg.lstsq(). NumPy returns a tuple with four elements, the first of which being the least-squares solutions and the others being essentially never used. Keras only returns the first value. This is done both to ensure consistency across backends (which cannot be achieved for the other values) and to simplify the API.

`op_lu_factor` *Computes the lower-upper decomposition of a square matrix.*

Description

Computes the lower-upper decomposition of a square matrix.

Usage

```
op_lu_factor(x)
```

Arguments

`x`	A tensor of shape `(..., M, M)`.

Value

A tuple of two tensors: a tensor of shape `(..., M, M)` containing the lower and upper triangular matrices and a tensor of shape `(..., M)` containing the pivots.

op_map *Map a function over leading array axes.*

Description

Like purrr::map() or base::lapply(), except inputs and outputs are in the form of stacked arrays. Consider using the op_vectorized_map() transform instead, unless you need to apply a function element by element for reduced memory usage or heterogeneous computation with other control flow primitives.

When xs is an array type, the semantics of op_map() match this implementation:

```
op_map <- function(xs, f) {
  xs |>
    op_unstack() |>
    lapply(f) |>
    op_stack()
}
```

Usage

```
op_map(xs, f)
```

Arguments

xs	Values over which to map along the leading axis.
f	Callable defines the function to apply element-wise over the first axis or axes of xs.

Value

Mapped values.

Examples

```
f <- function(x) x^2
xs <- op_arange(10)
ys <- op_map(xs, f)
ys
```

```
## tf.Tensor([ 1.  4.  9. 16. 25. 36. 49. 64. 81. 100.], shape=(10), dtype=float32)
```

```
f <- function(x) list(y1 = x^2, y2 = x * 10)  # Can have nested outputs
ys <- op_map(xs, f)
ys$y1
```

```
## tf.Tensor([ 1.  4.  9. 16. 25. 36. 49. 64. 81. 100.], shape=(10), dtype=float32)
```

```
ys$y2
```

```
## tf.Tensor([ 10.  20.  30.  40.  50.  60.  70.  80.  90. 100.], shape=(10), dtype=float32)
```

op_matmul *Matrix product of two tensors.*

Description

- If both tensors are 1-dimensional, the dot product (scalar) is returned.
- If either tensor is N-D, N > 2, it is treated as a stack of matrices residing in the last two indexes and broadcast accordingly.
- If the first tensor is 1-D, it is promoted to a matrix by prepending a 1 to its dimensions. After matrix multiplication the prepended 1 is removed.
- If the second tensor is 1-D, it is promoted to a matrix by appending a 1 to its dimensions. After matrix multiplication the appended 1 is removed.

Usage

```
op_matmul(x1, x2)
```

Arguments

x1	First tensor.
x2	Second tensor.

Value

Output tensor, matrix product of the inputs.

op_max *Return the maximum of a tensor or maximum along an axis.*

Description

Return the maximum of a tensor or maximum along an axis.

Usage

```
op_max(x, axis = NULL, keepdims = FALSE, initial = NULL)
```

Arguments

x	Input tensor.
axis	Axis or axes along which to operate. By default, flattened input is used.

keepdims	If this is set to TRUE, the axes which are reduced are left in the result as dimensions with size one. Defaults to FALSE.
initial	The minimum value of an output element. Defaults to NULL.

Value

Maximum of x.

Examples

```
(x <- op_convert_to_tensor(rbind(c(1, 3, 5), c(1, 5, 2))))

## tf.Tensor(
## [[1. 3. 5.]
##  [1. 5. 2.]], shape=(2, 3), dtype=float64)

op_max(x)

## tf.Tensor(5.0, shape=(), dtype=float64)

op_max(x, axis = 1)

## tf.Tensor([1. 5. 5.], shape=(3), dtype=float64)

op_max(x, axis = 1, keepdims = TRUE)

## tf.Tensor([[1. 5. 5.]], shape=(1, 3), dtype=float64)
```

`op_maximum` *Element-wise maximum of* `x1` *and* `x2`.

Description

Element-wise maximum of `x1` and `x2`.

Usage

```
op_maximum(x1, x2)

op_pmax(x1, x2)
```

Arguments

`x1`	First tensor.
`x2`	Second tensor.

Value

Output tensor, element-wise maximum of `x1` and `x2`.

op_max_pool *Max pooling operation.*

Description

Max pooling operation.

Usage

```
op_max_pool(
  inputs,
  pool_size,
  strides = NULL,
  padding = "valid",
  data_format = NULL
)
```

Arguments

inputs	Tensor of rank N+2. inputs has shape (batch_size,) + inputs_spatial_shape + (num_channels,) if data_format = "channels_last", or (batch_size, num_channels) + inputs_spatial_shape if data_format = "channels_first". Pooling happens over the spatial dimensions only.
pool_size	int or tuple/list of integers of size len(inputs_spatial_shape), specifying the size of the pooling window for each spatial dimension of the input tensor. If pool_size is int, then every spatial dimension shares the same pool_size.
strides	int or tuple/list of integers of size len(inputs_spatial_shape). The stride of the sliding window for each spatial dimension of the input tensor. If strides is int, then every spatial dimension shares the same strides.
padding	string, either "valid" or "same". "valid" means no padding is applied, and "same" results in padding evenly to the left/right or up/down of the input such that output has the same height/width dimension as the input when strides = 1.
data_format	A string, either "channels_last" or "channels_first". data_format determines the ordering of the dimensions in the inputs. If data_format = "channels_last", inputs is of shape (batch_size, ..., channels) while if data_format = "channels_first", inputs is of shape (batch_size, channels, ...).

Value

A tensor of rank N+2, the result of the max pooling operation.

`op_mean` *Compute the arithmetic mean along the specified axes.*

Description

Compute the arithmetic mean along the specified axes.

Usage

```
op_mean(x, axis = NULL, keepdims = FALSE)
```

Arguments

`x`	Input tensor.
`axis`	Axis or axes along which the means are computed. The default is to compute the mean of the flattened tensor.
`keepdims`	If this is set to `TRUE`, the axes which are reduced are left in the result as dimensions with size one.

Value

Output tensor containing the mean values.

op_median *Compute the median along the specified axis.*

Description

Compute the median along the specified axis.

Usage

```
op_median(x, axis = NULL, keepdims = FALSE)
```

Arguments

x	Input tensor.
axis	Axis or axes along which the medians are computed. Defaults to axis = NULL which is to compute the median(s) along a flattened version of the array.
keepdims	If this is set to TRUE, the axes which are reduce are left in the result as dimensions with size one.

Value

The output tensor.

`op_meshgrid` *Creates grids of coordinates from coordinate vectors.*

Description

Given `N` 1-D tensors `T0, T1, ..., TN-1` as inputs with corresponding lengths `S0, S1, ..., SN-1`, this creates an `N` N-dimensional tensors `G0, G1, ..., GN-1` each with shape `(S0, ..., SN-1)` where the output `Gi` is constructed by expanding `Ti` to the result shape.

Usage

```
op_meshgrid(..., indexing = "xy")
```

Arguments

`...`	1-D tensors representing the coordinates of a grid.
`indexing`	`"xy"` or `"ij"`. "xy" is cartesian; `"ij"` is matrix indexing of output. Defaults to `"xy"`.

Value

Sequence of N tensors.

Examples

```
x <- op_array(c(1, 2, 3), "int32")
y <- op_array(c(4, 5, 6), "int32")

c(grid_x, grid_y) %<-% op_meshgrid(x, y, indexing = "ij")
grid_x

## tf.Tensor(
## [[1 1 1]
##  [2 2 2]
##  [3 3 3]], shape=(3, 3), dtype=int32)

# array([[1, 1, 1],
#        [2, 2, 2],
#        [3, 3, 3]))
grid_y

## tf.Tensor(
## [[4 5 6]
##  [4 5 6]
##  [4 5 6]], shape=(3, 3), dtype=int32)

# array([[4, 5, 6],
#        [4, 5, 6],
#        [4, 5, 6]))
```

`op_min` *Return the minimum of a tensor or minimum along an axis.*

Description

Return the minimum of a tensor or minimum along an axis.

Usage

```
op_min(x, axis = NULL, keepdims = FALSE, initial = NULL)
```

Arguments

`x`	Input tensor.
`axis`	Axis or axes along which to operate. By default, flattened input is used.
`keepdims`	If this is set to `TRUE`, the axes which are reduced are left in the result as dimensions with size one. Defaults to `FALSE`.
`initial`	The maximum value of an output element. Defaults to `NULL`.

Value

Minimum of x.

Examples

```
(x <- op_convert_to_tensor(rbind(c(1, 3, 5), c(1, 5, 2))))

## tf.Tensor(
## [[1. 3. 5.]
##  [1. 5. 2.]], shape=(2, 3), dtype=float64)

op_min(x)

## tf.Tensor(1.0, shape=(), dtype=float64)

op_min(x, axis = 1)

## tf.Tensor([1. 3. 2.], shape=(3), dtype=float64)

op_min(x, axis = 1, keepdims = TRUE)

## tf.Tensor([[1. 3. 2.]], shape=(1, 3), dtype=float64)
```

op_minimum *Element-wise minimum of* x1 *and* x2.

Description

Element-wise minimum of x1 and x2.

Usage

```
op_minimum(x1, x2)

op_pmin(x1, x2)
```

Arguments

x1	First tensor.
x2	Second tensor.

Value

Output tensor, element-wise minimum of x1 and x2.

op_mod *Returns the element-wise remainder of division.*

Description

Note that this function is automatically called when using the R operator `%%` with a tensor.

```
(x <- op_arange(10))

## tf.Tensor([ 1.  2.  3.  4.  5.  6.  7.  8.  9. 10.], shape=(10), dtype=float32)

op_mod(x, 3)

## tf.Tensor([1. 2. 0. 1. 2. 0. 1. 2. 0. 1.], shape=(10), dtype=float32)

x %% 3

## tf.Tensor([1. 2. 0. 1. 2. 0. 1. 2. 0. 1.], shape=(10), dtype=float32)
```

Usage

```
op_mod(x1, x2)
```

Arguments

x1	First tensor.
x2	Second tensor.

Value

Output tensor, element-wise remainder of division.

`op_moments` *Calculates the mean and variance of* `x`.

Description

The mean and variance are calculated by aggregating the contents of `x` across `axes`. If `x` is 1-D and `axes = c(1)` this is just the mean and variance of a vector.

Usage

```
op_moments(x, axes, keepdims = FALSE, synchronized = FALSE)
```

Arguments

`x`	Input tensor.
`axes`	A list of axes which to compute mean and variance.
`keepdims`	If this is set to `TRUE`, the axes which are reduced are left in the result as dimensions with size one.

synchronized — Only applicable with the TensorFlow backend. If TRUE, synchronizes the global batch statistics (mean and variance) across all devices at each training step in a distributed training strategy. If FALSE, each replica uses its own local batch statistics.

Value

A list containing two tensors - mean and variance.

Examples

```
x <- op_convert_to_tensor(c(0, 1, 2, 3, 100), dtype = "float32")
op_moments(x, axes = c(1))

## [[1]]
## tf.Tensor(21.2, shape=(), dtype=float32)
##
## [[2]]
## tf.Tensor(1553.3601, shape=(), dtype=float32)
```

op_moveaxis *Move axes of a tensor to new positions.*

Description

Other axes remain in their original order.

Usage

```
op_moveaxis(x, source, destination)
```

Arguments

x	Tensor whose axes should be reordered.
source	Original positions of the axes to move. These must be unique.
destination	Destinations positions for each of the original axes. These must also be unique.

Value

Tensor with moved axes.

`op_multiply` *Multiply arguments element-wise.*

Description

Note that this function is automatically called when using the R operator `*` with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_multiply(x, x)

## tf.Tensor([ 1.  4.  9. 16.], shape=(4), dtype=float32)

x * x

## tf.Tensor([ 1.  4.  9. 16.], shape=(4), dtype=float32)
```

Usage

```
op_multiply(x1, x2)
```

Arguments

x1	First input tensor.
x2	Second input tensor.

Value

Output tensor, element-wise product of x1 and x2.

`op_multi_hot` *Encodes integer labels as multi-hot vectors.*

Description

This function encodes integer labels as multi-hot vectors, where each label is mapped to a binary value in the resulting vector.

Usage

```
op_multi_hot(
  inputs,
  num_classes,
  axis = -1L,
  dtype = NULL,
  sparse = FALSE,
  ...
)
```

Arguments

`inputs`	Tensor of integer labels to be converted to multi-hot vectors.
`num_classes`	Integer, the total number of unique classes.
`axis`	(optional) Axis along which the multi-hot encoding should be added. Defaults to `-1`, which corresponds to the last dimension.
`dtype`	(optional) The data type of the resulting tensor. Default is backend's float type.
`sparse`	Whether to return a sparse tensor; for backends that support sparse tensors.
`...`	For forward/backwards compatability

Value

Tensor: The multi-hot encoded tensor.

Examples

```
data <- op_convert_to_tensor(c(0, 4))
op_multi_hot(data, num_classes = 5)

## tf.Tensor([1. 0. 0. 0. 1.], shape=(5), dtype=float32)
```

`op_nan_to_num` *Replace NaN with zero and infinity with large finite numbers.*

Description

Replace NaN with zero and infinity with large finite numbers.

Usage

```
op_nan_to_num(x, nan = 0, posinf = NULL, neginf = NULL)
```

Arguments

`x`	Input data.
`nan`	Optional float or int. Value to replace `NaN` entries with.
`posinf`	Optional float or int. Value to replace positive infinity with.
`neginf`	Optional float or int. Value to replace negative infinity with.

Value

x, with non-finite values replaced.

Example

```
(x <- op_convert_to_tensor(c(1, NaN, -Inf, Inf)))

## tf.Tensor([  1.  nan -inf  inf], shape=(4), dtype=float64)

op_nan_to_num(x)

## tf.Tensor([ 1.00000000e+000  0.00000000e+000 -1.79769313e+308  1.79769313e+308], shape=(4), dtype=f

op_nan_to_num(x, nan = -1, posinf = 2, neginf = -2)

## tf.Tensor([ 1. -1. -2.  2.], shape=(4), dtype=float64)
```

op_ndim *Return the number of dimensions of a tensor.*

Description

Return the number of dimensions of a tensor.

Usage

```
op_ndim(x)
```

Arguments

x	Input tensor.

Value

The number of dimensions in x.

`op_negative` *Numerical negative, element-wise.*

Description

Note that this function is automatically called when using the unary R operator `-` with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)
```

```
op_negative(x)

## tf.Tensor([-1. -2. -3. -4.], shape=(4), dtype=float32)

-x

## tf.Tensor([-1. -2. -3. -4.], shape=(4), dtype=float32)
```

Usage

```
op_negative(x)
```

Arguments

x	Input tensor.

Value

Output tensor, y = -x.

op_nonzero *Return the indices of the elements that are non-zero.*

Description

Return the indices of the elements that are non-zero.

Usage

```
op_nonzero(x)
```

Arguments

x	Input tensor.

Details

Example:

`op_nonzero()` indices can be used with `<tensor>@r[`

```
(x <- op_scatter(indices = rbind(1, 5, 10), values = c(1, 2, 3), shape = c(10)))

## tf.Tensor([1. 0. 0. 0. 2. 0. 0. 0. 0. 3.], shape=(10), dtype=float64)

(nz <- op_nonzero(x))
```

```
## tf.Tensor(
## [[ 1]
##  [ 5]
##  [10]], shape=(3, 1), dtype=int32)

x@r[nz]

## tf.Tensor([1. 2. 3.], shape=(3), dtype=float64)

# same as `x@r[nz]`
x@r[x != 0]

## tf.Tensor([1. 2. 3.], shape=(3), dtype=float64)

x@r[op_cast(x, "bool")]

## tf.Tensor([1. 2. 3.], shape=(3), dtype=float64)

# 2d example
(x2 <- op_stack(c(x, op_roll(x, 1), op_roll(x, 2))))

## tf.Tensor(
## [[1. 0. 0. 0. 2. 0. 0. 0. 0. 3.]
##  [3. 1. 0. 0. 0. 2. 0. 0. 0. 0.]
##  [0. 3. 1. 0. 0. 0. 2. 0. 0. 0.]], shape=(3, 10), dtype=float64)

x2@r[op_nonzero(x2)]

## tf.Tensor([1. 2. 3. 3. 1. 2. 3. 1. 2.], shape=(9), dtype=float64)

x3 <- op_stack(c(x2, x2*1.1))
x3@r[op_nonzero(x3)]

## tf.Tensor([1.  2.  3.  3.  1.  2.  3.  1.  2.  1.1 2.2 3.3 3.3 1.1 2.2 3.3 1.1 2.2], shape=(18), dtype=fl
```

Value

Indices of elements that are non-zero.

`op_norm` *Matrix or vector norm.*

Description

This function is able to return one of eight different matrix norms, or one of an infinite number of vector norms (described below), depending on the value of the `ord` parameter.

Usage

```
op_norm(x, ord = NULL, axis = NULL, keepdims = FALSE)
```

Arguments

x	Input tensor.
ord	Order of the norm (see table under Notes). The default is NULL.
axis	If axis is an integer, it specifies the axis of x along which to compute the vector norms. If axis is a length 2 vector, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed.
keepdims	If this is set to TRUE, the axes which are reduced are left in the result as dimensions with size one.

Value

Norm of the matrix or vector(s).

Note

For values of ord < 1, the result is, strictly speaking, not a mathematical 'norm', but it may still be useful for various numerical purposes. The following norms can be calculated:

- For matrices:
  - ord=NULL: Frobenius norm
  - ord="fro": Frobenius norm
  - ord="nuc": nuclear norm
  - ord=Inf: max(sum(abs(x), axis=2))
  - ord=-Inf: min(sum(abs(x), axis=2))
  - ord=0: not supported
  - ord=1: max(sum(abs(x), axis=1))
  - ord=-1: min(sum(abs(x), axis=1))
  - ord=2: 2-norm (largest sing. value)
  - ord=-2: smallest singular value
  - other: not supported
- For vectors:
  - ord=NULL: 2-norm
  - ord="fro": not supported
  - ord="nuc": not supported
  - ord=Inf: max(abs(x))
  - ord=-Inf: min(abs(x))
  - ord=0: sum(x != 0)
  - ord=1: as below
  - ord=-1: as below
  - ord=2: as below
  - ord=-2: as below
  - other: sum(abs(x)^ord)^(1/ord)

Examples

```
x <- op_reshape(op_arange(9, dtype="float32") - 4, c(3, 3))
op_norm(x)

## tf.Tensor(8.306623, shape=(), dtype=float32)

# 7.7459664
```

op_normalize *Normalizes* x *over the specified axis.*

Description

It is defined as: op_normalize(x) = x / max(norm(x), epsilon).

Usage

```
op_normalize(x, axis = -1L, order = 2L, epsilon = NULL)
```

Arguments

x	Input tensor.
axis	The axis or axes along which to perform normalization. Default to -1.
order	The exponent value in the norm formulation. Defaults to 2.
epsilon	A lower bound value for the norm. Defaults to config_epsilon().

Value

The normalized array.

Examples

```
x <- op_convert_to_tensor(rbind(c(1, 2, 3), c(4, 5, 6)))
x_norm <- op_normalize(x)
x_norm

## tf.Tensor(
## [[0.26726124 0.53452248 0.80178373]
##  [0.45584231 0.56980288 0.68376346]], shape=(2, 3), dtype=float64)
```

op_not_equal *Return* (x1 != x2) *element-wise.*

Description

Note that this function is automatically called when using the R operator != with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_not_equal(x, 2)

## tf.Tensor([ True False  True  True], shape=(4), dtype=bool)

x != 2

## tf.Tensor([ True False  True  True], shape=(4), dtype=bool)
```

Usage

```
op_not_equal(x1, x2)
```

Arguments

x1	First input tensor.
x2	Second input tensor.

Value

Output tensor, element-wise comparison of x1 and x2.

op_ones *Return a new tensor of given shape and type, filled with ones.*

Description

Return a new tensor of given shape and type, filled with ones.

Usage

```
op_ones(shape, dtype = NULL)
```

Arguments

shape	Shape of the new tensor.
dtype	Desired data type of the tensor.

Value

Tensor of ones with the given shape and dtype.

`op_ones_like` *Return a tensor of ones with the same shape and type of* `x`.

Description

Return a tensor of ones with the same shape and type of `x`.

Usage

```
op_ones_like(x, dtype = NULL)
```

Arguments

`x`	Input tensor.
`dtype`	Overrides the data type of the result.

Value

A tensor of ones with the same shape and type as `x`.

op_one_hot *Converts integer tensor* x *into a one-hot tensor.*

Description

The one-hot encoding is a representation where each integer value is converted into a binary vector with a length equal to num_classes, and the index corresponding to the integer value is marked as 1, while all other indices are marked as 0.

Usage

```
op_one_hot(
  x,
  num_classes,
  axis = -1L,
  dtype = NULL,
  sparse = FALSE,
  zero_indexed = FALSE
)
```

Arguments

x	Integer tensor to be encoded. The shape can be arbitrary, but the dtype should be integer. R factors are coerced to integer.
num_classes	Number of classes for the one-hot encoding. If x is a factor and num_classes is NULL or missing, then levels(x) is used.
axis	Axis along which the encoding is performed. -1 represents the last axis. Defaults to -1.
dtype	(Optional) Data type of the output tensor. If not provided, it defaults to the default data type of the backend.
sparse	Whether to return a sparse tensor; for backends that support sparse tensors.
zero_indexed	If TRUE, treats indices as zero-based (0 encodes to first position); if FALSE (default), treats indices as one-based (1 encodes to first position).

Value

Integer tensor: One-hot encoded tensor with the same shape as x except for the specified axis dimension, which will have a length of num_classes. The dtype of the output tensor is determined by dtype or the default data type of the backend.

Examples

```
x <- op_array(c(2, 4, 3, 1), "int32")
op_one_hot(x, num_classes = 4)

## tf.Tensor(
## [[0. 1. 0. 0.]
##  [0. 0. 0. 1.]
##  [0. 0. 1. 0.]
##  [1. 0. 0. 0.]], shape=(4, 4), dtype=float32)
```

```
op_one_hot(x - 1, num_classes = 4, zero_indexed = TRUE)
```

```
## tf.Tensor(
## [[0. 1. 0. 0.]
##  [0. 0. 0. 1.]
##  [0. 0. 1. 0.]
##  [1. 0. 0. 0.]], shape=(4, 4), dtype=float32)
```

`op_outer` *Compute the outer product of two vectors.*

Description

Given two vectors `x1` and `x2`, the outer product is:

```
out[i, j] = x1[i] * x2[j]
```

Usage

```
op_outer(x1, x2)
```

Arguments

x1	First input tensor.
x2	Second input tensor.

Value

Outer product of x1 and x2.

op_pad *Pad a tensor.*

Description

Pad a tensor.

Usage

```
op_pad(x, pad_width, mode = "constant", constant_values = NULL)
```

Arguments

x	Tensor to pad.
pad_width	Number of values padded to the edges of each axis. `((before_1, after_1), ...(before_N, after_N)` unique pad widths for each axis. `((before, after),)` yields same before and after pad for each axis. `(pad,)` or `int` is a shortcut for `before = after = pad` width for all axes.
mode	One of `"constant"`, `"edge"`, `"linear_ramp"`, `"maximum"`, `"mean"`, `"median"`, `"minimum"`, `"reflect"`, `"symmetric"`, `"wrap"`, `"empty"`, `"circular"`. Defaults to `"constant"`.
constant_values	Value to pad with if `mode == "constant"`. Defaults to `0`. A `ValueError` is raised if not `NULL` and `mode != "constant"`.

Value

Padded tensor.

Note

Torch backend only supports modes `"constant"`, `"reflect"`, `"symmetric"` and `"circular"`. Only Torch backend supports `"circular"` mode.

Note: Tensorflow backend only supports modes `"constant"`, `"reflect"` and `"symmetric"`.

`op_polar` *Constructs a complex tensor whose elements are Cartesian*

Description

coordinates corresponding to the polar coordinates with absolute value abs and angle angle.

The operation is numerically equivalent to `torch.polar()`. It is not equivalent to `scipy.lingalg.polar()` which performs Singular Value Decomposition.

Given the magnitude (abs_) and angle (angle), this function computes the corresponding complex number in the form of `real + imaginary * 1i`, where:

- `real = abs_ * cos(angle)`
- `imaginary = abs_ * sin(angle)`

Usage

```
op_polar(abs_, angle)
```

Arguments

abs_	The magnitude (absolute value) of the complex number.
angle	The angle (in radians) of the complex number.

Value

A complex number (or array of complex numbers) with the same shape as abs_ and angle.

Examples

```
abs_ <- random_normal(c(1, 2))
angle <- random_normal(c(1, 2))
op_shape(op_polar(abs_, angle))

## shape(1, 2)

op_polar(abs_, angle)

## tf.Tensor([[-0.10252866-1.2460487j -0.2586355 -1.0352845j]], shape=(1, 2), dtype=complex64)
```

op_power *First tensor elements raised to powers from second tensor, element-wise.*

Description

Note that this function is automatically called when using the R operator ^ with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_power(2, x)

## tf.Tensor([ 2.  4.  8. 16.], shape=(4), dtype=float32)

2 ^ x

## tf.Tensor([ 2.  4.  8. 16.], shape=(4), dtype=float32)
```

Usage

```
op_power(x1, x2)
```

Arguments

x1	The bases.
x2	The exponents.

Value

Output tensor, the bases in `x1` raised to the exponents in `x2`.

op_prod *Return the product of tensor elements over a given axis.*

Description

Return the product of tensor elements over a given axis.

Usage

```
op_prod(x, axis = NULL, keepdims = FALSE, dtype = NULL)
```

Arguments

x	Input tensor.
axis	Axis or axes along which a product is performed. The default, axis = NULL, will compute the product of all elements in the input tensor.
keepdims	If this is set to TRUE, the axes which are reduce are left in the result as dimensions with size one.
dtype	Data type of the returned tensor.

Value

Product of elements of x over the given axis or axes.

`op_psnr` *Peak Signal-to-Noise Ratio (PSNR) function.*

Description

This function computes the Peak Signal-to-Noise Ratio between two signals, `x1` and `x2`. PSNR is a measure of the quality of a reconstructed signal. The higher the PSNR, the closer the reconstructed signal is to the original signal. Note that it can become negative when the signal power is smaller that the noise power.

Usage

```
op_psnr(x1, x2, max_val)
```

Arguments

`x1`	The first input signal.
`x2`	The second input signal. Must have the same shape as `x1`.
`max_val`	The maximum possible value in the signals.

Value

float: The PSNR value between `x1` and `x2`.

Examples

```
x1 <- random_normal(c(2, 4, 4, 3))
x2 <- random_normal(c(2, 4, 4, 3))
max_val <- 1.0
op_psnr(x1, x2, max_val)

## tf.Tensor(-3.5293808, shape=(), dtype=float32)
```

op_qr *Computes the QR decomposition of a tensor.*

Description

Computes the QR decomposition of a tensor.

Usage

```
op_qr(x, mode = "reduced")
```

Arguments

x	Input tensor of shape (..., M, N).
mode	A string specifying the mode of the QR decomposition. • 'reduced': Returns the reduced QR decomposition. (default) • 'complete': Returns the complete QR decomposition.

Value

A list containing two tensors. The first tensor of shape (..., M, K) is the orthogonal matrix q and the second tensor of shape (..., K, N)is the upper triangular matrixr, where K = min(M, N)'.

Examples

```
x <- op_convert_to_tensor(rbind(c(1, 2), c(3, 4), c(5, 6)))
op_qr(x)
```

```
## $q
## tf.Tensor(
## [[-0.16903085  0.89708523]
##  [-0.50709255  0.27602622]
##  [-0.84515425 -0.34503278]], shape=(3, 2), dtype=float64)
##
## $r
## tf.Tensor(
## [[-5.91607978 -7.43735744]
##  [ 0.          0.82807867]], shape=(2, 2), dtype=float64)
```

```
c(q, r) %<-% op_qr(x)
```

`op_quantile` *Compute the q-th quantile(s) of the data along the specified axis.*

Description

Compute the q-th quantile(s) of the data along the specified axis.

Usage

```
op_quantile(x, q, axis = NULL, method = "linear", keepdims = FALSE)
```

Arguments

x	Input tensor.
q	Probability or sequence of probabilities for the quantiles to compute. Values must be between 0 and 1 inclusive.
axis	Axis or axes along which the quantiles are computed. Defaults to axis=NULL which is to compute the quantile(s) along a flattened version of the array.
method	A string specifies the method to use for estimating the quantile. Available methods are "linear", "lower", "higher", "midpoint", and "nearest". Defaults to "linear". If the desired quantile lies between two data points i < j: • "linear": i + (j - i) * fraction, where fraction is the fractional part of the index surrounded by i and j. • "lower": i. • "higher": j. • "midpoint": (i + j) / 2 • "nearest": i or j, whichever is nearest.
keepdims	If this is set to TRUE, the axes which are reduce are left in the result as dimensions with size one.

Value

The quantile(s). If q is a single probability and axis = NULL, then the result is a scalar. If multiple probabilities levels are given, first axis of the result corresponds to the quantiles. The other axes are the axes that remain after the reduction of x.

`op_ravel` *Return a contiguous flattened tensor.*

Description

A 1-D tensor, containing the elements of the input, is returned.

Usage

```
op_ravel(x)
```

Arguments

x	Input tensor.

Value

Output tensor.

`op_real` *Return the real part of the complex argument.*

Description

Return the real part of the complex argument.

Usage

```
op_real(x)
```

Arguments

x	Input tensor.

Value

The real component of the complex argument.

op_rearrange *Rearranges the axes of a Keras tensor according to a specified pattern,*

Description

einops-style.

Usage

```
op_rearrange(tensor, pattern, ...)
```

Arguments

tensor	Input Keras tensor.
pattern	String describing the rearrangement in einops notation.
...	axes_lengths, named arguments specifying lengths of axes when axes decomposition is used.

Value

Tensor: A Keras tensor with rearranged axes.

Follows the logic of:

1. If decomposition is needed, reshape to match decomposed dimensions.
2. Permute known and inferred axes to match the form of the output.
3. Reshape to match the desired output shape.

Example Usage:

```
images <- op_ones(c(32, 30, 40, 3)) # BHWC format

# Reordering to BCHW
op_rearrange(images, 'b h w c -> b c h w') |> op_shape()

## shape(32, 3, 30, 40)
```

```
# "Merge" along first axis - concat images from a batch
op_rearrange(images, 'b h w c -> (b h) w c') |> op_shape()

## shape(960, 40, 3)

# "Merge" along second axis - concat images horizontally
op_rearrange(images, 'b h w c -> h (b w) c') |> op_shape()

## shape(30, 1280, 3)

# Flatten images into a CHW vector
op_rearrange(images, 'b h w c -> b (c h w)') |> op_shape()

## shape(32, 3600)

# Decompose H and W axes into 4 smaller patches
op_rearrange(images, 'b (h1 h) (w1 w) c -> (b h1 w1) h w c', h1 = 2, w1 = 2) |> op_shape()

## shape(128, 15, 20, 3)

# Space-to-depth decomposition of input axes
op_rearrange(images, 'b (h h1) (w w1) c -> b h w (c h1 w1)', h1 = 2, w1 = 2) |> op_shape()

## shape(32, 15, 20, 12)
```

`op_reciprocal` *Return the reciprocal of the argument, element-wise.*

Description

Calculates `1/x`.

Usage

```
op_reciprocal(x)
```

Arguments

x	Input tensor.

Value

Output tensor, element-wise reciprocal of x.

`op_relu` *Rectified linear unit activation function.*

Description

It is defined as `f(x) = max(0, x)`.

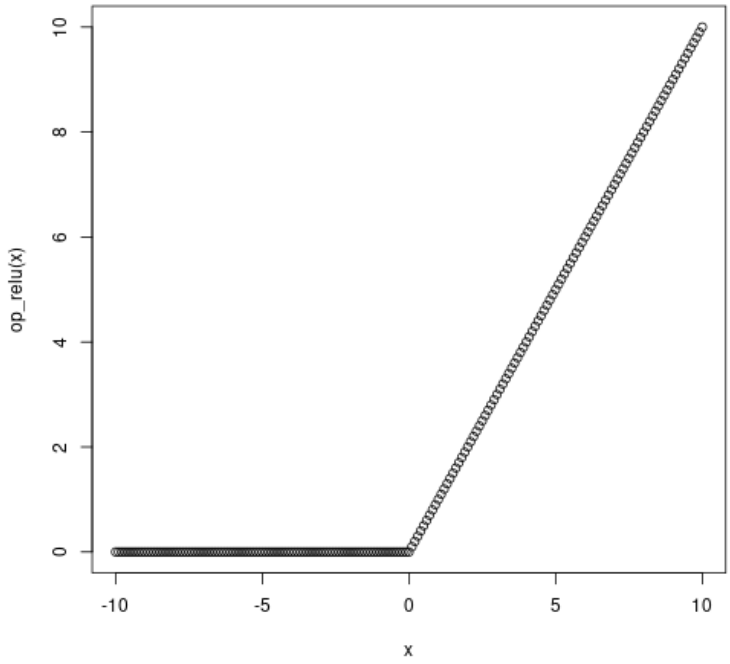
Usage

```
op_relu(x)
```

Arguments

`x`	Input tensor.

Value



A tensor with the same shape as `x`.

Examples

```
x1 <- op_convert_to_tensor(c(-1, 0, 1, 0.2))
op_relu(x1)
```

```
## tf.Tensor([0.  0.  1.  0.2], shape=(4), dtype=float64)
```

```
x <- seq(-10, 10, .1)
plot(x, op_relu(x))
```

op_relu6 *Rectified linear unit activation function with upper bound of 6.*

Description

It is defined as `f(x) = op_clip(x, 0, 6)`.

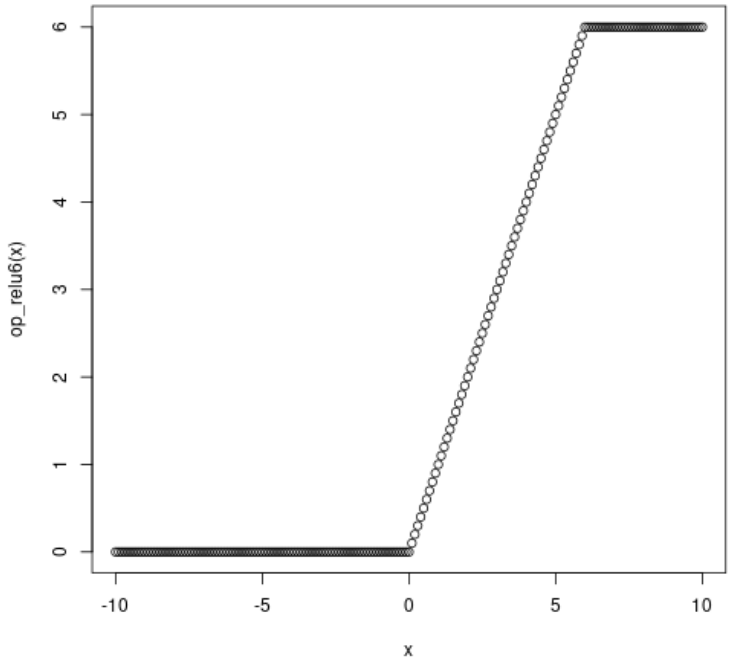
Usage

```
op_relu6(x)
```

Arguments

x	Input tensor.

Value



A tensor with the same shape as `x`.

Examples

```
x <- op_convert_to_tensor(c(-3, -2, 0.1, 0.2, 6, 8))
op_relu6(x)
```

```
## tf.Tensor([0.  0.  0.1 0.2 6.  6. ], shape=(6), dtype=float64)
```

```
x <- seq(-10, 10, .1)
plot(x, op_relu6(x))
```

op_repeat *Repeat each element of a tensor after themselves.*

Description

Repeat each element of a tensor after themselves.

Usage

```
op_repeat(x, repeats, axis = NULL)
```

Arguments

x	Input tensor.
repeats	The number of repetitions for each element.
axis	The axis along which to repeat values. By default, use the flattened input array, and return a flat output array.

Value

Output tensor.

`op_reshape` *Gives a new shape to a tensor without changing its data.*

Description

Gives a new shape to a tensor without changing its data.

Usage

```
op_reshape(x, newshape)
```

Arguments

`x`	Input tensor.
`newshape`	The new shape should be compatible with the original shape. One shape dimension can be `-1` in which case the value is inferred from the length of the array and remaining dimensions.

Value

The reshaped tensor.

op_rfft *Real-valued Fast Fourier Transform along the last axis of the input.*

Description

Computes the 1D Discrete Fourier Transform of a real-valued signal over the inner-most dimension of input.

Since the Discrete Fourier Transform of a real-valued signal is Hermitian-symmetric, RFFT only returns the `fft_length / 2 + 1` unique components of the FFT: the zero-frequency term, followed by the `fft_length / 2` positive-frequency terms.

Along the axis RFFT is computed on, if `fft_length` is smaller than the corresponding dimension of the input, the dimension is cropped. If it is larger, the dimension is padded with zeros.

Usage

```
op_rfft(x, fft_length = NULL)
```

Arguments

`x`	Input tensor.
`fft_length`	An integer representing the number of the fft length. If not specified, it is inferred from the length of the last axis of `x`. Defaults to `NULL`.

Value

A list containing two tensors - the real and imaginary parts of the output.

Examples

```
x <- op_convert_to_tensor(c(0, 1, 2, 3, 4))
op_rfft(x)
```

```
## [[1]]
## tf.Tensor([10.  -2.5 -2.5], shape=(3), dtype=float64)
##
## [[2]]
## tf.Tensor([0.         3.4409548  0.81229924], shape=(3), dtype=float64)
```

```
op_rfft(x, 3)
```

```
## [[1]]
## tf.Tensor([ 3.  -1.5], shape=(2), dtype=float64)
##
## [[2]]
## tf.Tensor([0.        0.8660254], shape=(2), dtype=float64)
```

`op_right_shift` *Shift the bits of an integer to the right.*

Description

Bits are shifted to the right `y`. Because the internal representation of numbers is in binary format, this operation is equivalent to dividing `x` by `2^y`.

Usage

```
op_right_shift(x, y)
```

Arguments

`x`	Input integer tensor.
`y`	Input integer tensor.

Value

Result tensor.

`op_rms_normalization` *Performs Root Mean Square (RMS) normalization on* `x`.

Description

The Keras operation implements the operation as described in Root Mean Square Layer Normalization by Biao Zhang et al.

The operation is different from LayerNormalization with RMS scaling.

It is defined as `rms_normalization(x) = x * rsqrt(mean(square(x))) * scale`

Usage

```
op_rms_normalization(x, scale = 1L, axis = -1L, epsilon = NULL)
```

Arguments

`x`	Input tensor.
`scale`	Optional scaling factor for the normalization.
`axis`	The axis or axes along which to perform normalization. Default to -1.
`epsilon`	A lower bound value for the norm. Defaults to `config_epsilon()`.

Value

The normalized array.

Examples

```
x <- random_uniform(c(1, 10))
x_norm <- op_rms_normalization(x, scale = 10)
x_norm
```

`op_roll` *Roll tensor elements along a given axis.*

Description

Elements that roll beyond the last position are re-introduced at the first.

Usage

```
op_roll(x, shift, axis = NULL)
```

Arguments

`x`	Input tensor.

shift	The number of places by which elements are shifted.
axis	The axis along which elements are shifted. By default, the array is flattened before shifting, after which the original shape is restored.

Value

Output tensor.

`op_rot90` *Rotate an array by 90 degrees in the plane specified by axes.*

Description

This function rotates an array counterclockwise by 90 degrees `k` times in the plane specified by `axes`. Supports arrays of two or more dimensions.

Usage

```
op_rot90(array, k = 1L, axes = list(1L, 2L))
```

Arguments

`array`	Input array to rotate.
`k`	Number of times the array is rotated by 90 degrees.
`axes`	A tuple of two integers specifying the plane of rotation (defaults to `(1, 2)`).

Value

Rotated array.

Examples

```
m <- 1:4 |> op_reshape(c(2, 2))
m

## tf.Tensor(
## [[1 2]
##  [3 4]], shape=(2, 2), dtype=int32)

op_rot90(m)

## tf.Tensor(
## [[2 4]
##  [1 3]], shape=(2, 2), dtype=int32)

m <- 1:8 |> op_reshape(c(2, 2, 2))
m
```

```
## tf.Tensor(
## [[[1 2]
##   [3 4]]
##
##  [[5 6]
##   [7 8]]], shape=(2, 2, 2), dtype=int32)
```

```
op_rot90(m, k = 1, axes = c(2, 3))
```

```
## tf.Tensor(
## [[[2 4]
##   [1 3]]
##
##  [[6 8]
##   [5 7]]], shape=(2, 2, 2), dtype=int32)
```

op_round *Evenly round to the given number of decimals.*

Description

Evenly round to the given number of decimals.

Usage

```
op_round(x, decimals = 0L)
```

Arguments

x	Input tensor.
decimals	Number of decimal places to round to. Defaults to 0.

Value

Output tensor.

`op_rsqrt` *Computes reciprocal of square root of x element-wise.*

Description

Computes reciprocal of square root of x element-wise.

Usage

```
op_rsqrt(x)
```

Arguments

x	input tensor

Value

A tensor with the same dtype as `x`.

Examples

```
x <- op_convert_to_tensor(c(1, 10, 100))
op_rsqrt(x)

## tf.Tensor([1.         0.31622777 0.1       ], shape=(3), dtype=float64)

# array([1, 0.31622776, 0.1], dtype=float32)
```

`op_saturate_cast` *Performs a safe saturating cast to the desired dtype.*

Description

Saturating cast prevents data type overflow when casting to `dtype` with smaller values range. E.g. `op_cast(c(-1, 256), "float32") |> op_cast("uint8")` returns `c(255, 0)`, but `op_cast(c(-1, 256), "float32") |> op_saturate_cast("uint8")` returns `c(0, 255)`.

Usage

```
op_saturate_cast(x, dtype)
```

Arguments

`x`	A tensor or variable.
`dtype`	The target type.

Value

A safely casted tensor of the specified `dtype`.

Examples

Image resizing with bicubic interpolation may produce values outside original range.

```
image2x2 <- np_array(as.integer(c(0, 1, 254, 255)), "uint8") |>
  array_reshape(c(1, 2, 2, 1))
image4x4 <- image2x2 |>
  tensorflow::tf$image$resize(shape(4, 4), method="bicubic")
image4x4 |> as.array() |> drop()
```

```
##           [,1]      [,2]      [,3]      [,4]
## [1,] -22.50000 -22.20462 -21.61891 -21.32353
## [2,]  52.52605  52.82143  53.40715  53.70253
## [3,] 201.29752 201.59288 202.17859 202.47395
## [4,] 276.32355 276.61893 277.20465 277.50006
```

Casting this resized image back to `uint8` will cause overflow.

```
image4x4_casted <- op_cast(image4x4, "uint8")
image4x4_casted |> as.array() |> drop()
```

```
##      [,1] [,2] [,3] [,4]
## [1,]  234  234  235  235
## [2,]   52   52   53   53
## [3,]  201  201  202  202
## [4,]   20   20   21   21
```

Saturate casting to `uint8` will clip values to `uint8` range before casting and will not cause overflow.

```
image4x4_saturate_casted <- image4x4 |> op_saturate_cast("uint8")
image4x4_saturate_casted |> as.array() |> drop()
```

```
##      [,1] [,2] [,3] [,4]
## [1,]    0    0    0    0
## [2,]   52   52   53   53
## [3,]  201  201  202  202
## [4,]  255  255  255  255
```

op_scan *Scan a function over leading array axes while carrying along state.*

Description

When the type of xs is an array type or NULL, and the type of ys is an array type, the semantics of op_scan() are given roughly by this implementation:

```
op_scan <- function(f, init, xs = NULL, length = NULL) {
  xs <- xs %||% vector("list", length)
  if(!is.list(xs))
    xs <- op_unstack(xs)
  ys <- vector("list", length(xs))
  carry <- init
  for (i in seq_along(xs)) {
    c(carry, y) %<-% f(carry, xs[[i]])
    ys[[i]] <- y
  }
  list(carry, op_stack(ys))
}
```

The loop-carried value `carry` (`init`) must hold a fixed shape and dtype across all iterations.

In TensorFlow, `y` must match `carry` in shape and dtype. This is not required in other backends.

Usage

```
op_scan(f, init, xs = NULL, length = NULL, reverse = FALSE, unroll = 1L)
```

Arguments

`f`	Callable defines the logic for each loop iteration. This accepts two arguments where the first is a value of the loop carry and the second is a slice of `xs` along its leading axis. This callable returns a pair where the first represents a new value for the loop carry and the second represents a slice of the output.
`init`	The initial loop carry value. This can be a scalar, tensor, or any nested structure. It must match the structure of the first element returned by `f`.
`xs`	Optional value to scan along its leading axis. This can be a tensor or any nested structure. If `xs` is not provided, you must specify `length` to define the number of loop iterations. Defaults to `NULL`.
`length`	Optional integer specifying the number of loop iterations. If `length` is not provided, it defaults to the sizes of leading axis of the arrays in `xs`. Defaults to `NULL`.
`reverse`	Optional boolean specifying whether to run the scan iteration forward or in reverse, equivalent to reversing the leading axes of the arrays in both `xs` and in `ys`.
`unroll`	Optional positive integer or boolean specifying how many scan iterations to unroll within a single iteration of a loop. If an integer is provided, it determines how many unrolled loop iterations to run within a single rolled iteration of the loop. If a boolean is provided, it will determine if the loop is completely unrolled (`unroll=TRUE`) or left completely unrolled (`unroll=FALSE`). Note that unrolling is only supported by JAX and TensorFlow backends.

Value

A pair where the first element represents the final loop carry value and the second element represents the stacked outputs of `f` when scanned over the leading axis of the inputs.

Examples

```
sum_fn <- function(c, x) list(c + x, c + x)
init <- op_array(0L)
xs <- op_array(1:5)
c(carry, result) %<-% op_scan(sum_fn, init, xs)
carry

## tf.Tensor(15, shape=(), dtype=int32)

result
```

```
## tf.Tensor([ 1  3  6 10 15], shape=(5), dtype=int32)
```

op_scatter *Returns a tensor of shape* shape *where* indices *are set to* values.

Description

At a high level, this operation does zeros[indices] = updates and returns the output. It is equivalent to:

```
output <- op_scatter_update(op_zeros(shape), indices, values)
```

Usage

```
op_scatter(indices, values, shape)
```

Arguments

indices	A tensor or list specifying indices for the values in values.
values	A tensor, the values to be set at indices.
shape	Shape of the output tensor.

Value

A tensor of shape shape where indices are set to values.

Examples

```
op_scatter(indices = rbind(1), values = 1, shape = c(5))

## tf.Tensor([1. 0. 0. 0. 0.], shape=(5), dtype=float64)

op_scatter(indices = rbind(1, 3), values = 1:2, shape = c(5))

## tf.Tensor([1 0 2 0 0], shape=(5), dtype=int32)
```

```
indices <- rbind(c(1, 2), c(2, 2))
values <- op_array(c(1, 1))
op_scatter(indices, values, shape = c(2, 2))

## tf.Tensor(
## [[0. 1.]
##  [0. 1.]], shape=(2, 2), dtype=float32)
```

`op_scatter_update` *Update inputs via updates at scattered (sparse) indices.*

Description

At a high level, this operation does `inputs[indices] <- updates`. Assume `inputs` is a tensor of shape `(D1, D2, ..., Dn)`, there are 2 main usages of `scatter_update`.

1. `indices` is a 2D tensor of shape `(num_updates, n)`, where `num_updates` is the number of updates to perform, and `updates` is a 1D tensor of shape `(num_updates)`. For example, if `inputs` is `op_zeros(c(4, 4, 4))`, and we want to update `inputs[2, 3, 4]` and `inputs[1, 2, 4]` as 1, then we can use:

```
inputs <- op_zeros(c(4, 4, 4))
indices <- rbind(c(2, 3, 4),
                 c(1, 2, 4))
updates <- op_array(c(1, 1), "float32")
op_scatter_update(inputs, indices, updates)
```

```
## tf.Tensor(
## [[[0. 0. 0. 0.]
##   [0. 0. 0. 1.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]]
##
##  [[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 1.]
##   [0. 0. 0. 0.]]
##
```

```
##  [[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]]
##
##  [[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]]], shape=(4, 4, 4), dtype=float32)
```

2 `indices` is a 2D tensor of shape `(num_updates, k)`, where `num_updates` is the number of updates to perform, and `k` (`k <= n`) is the size of each index in `indices`. `updates` is a `n - k`-D tensor of shape `(num_updates, shape(inputs)[-(1:k)])`. For example, if `inputs <- op_zeros(c(4, 4, 4))`, and we want to update `inputs[1, 2, ]` and `inputs[2, 3, ]` as `[1, 1, 1, 1]`, then `indices` would have shape `(num_updates, 2)` (`k = 2`), and `updates` would have shape `(num_updates, 4)` (`shape(inputs)[3:4] == 4`). See the code below:

```
inputs <- op_zeros(c(4, 4, 4))
indices <- rbind(c(2, 3),
                 c(3, 4))
updates <- op_array(rbind(c(1, 1, 1, 1),
                          c(1, 1, 1, 1)),
                    "float32")
op_scatter_update(inputs, indices, updates)
```

```
## tf.Tensor(
## [[[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]]
##
##  [[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [1. 1. 1. 1.]
##   [0. 0. 0. 0.]]
##
##  [[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [1. 1. 1. 1.]]
##
##  [[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]]], shape=(4, 4, 4), dtype=float32)
```

Usage

```
op_scatter_update(inputs, indices, updates)
```

Arguments

inputs	A tensor, the tensor to be updated.
indices	A tensor or list of shape (N, inputs$ndim), specifying indices to update. N is the number of indices to update, must be equal to the first dimension of updates.
updates	A tensor, the new values to be put to inputs at indices.

Value

A tensor, has the same shape and dtype as inputs.

`op_searchsorted` *Perform a binary search*

Description

Perform a binary search, returning indices for insertion of `values` into `sorted_sequence` that maintain the sorting order.

Usage

```
op_searchsorted(sorted_sequence, values, side = "left", zero_indexed = FALSE)
```

Arguments

`sorted_sequence`	1-D input tensor, sorted along the innermost dimension.
`values`	N-D tensor of query insertion values.
`side`	`'left'` or `'right'`, specifying the direction in which to insert for the equality case (tie-breaker).
`zero_indexed`	If `TRUE`, the returned indices are zero-based (`0` encodes to first position); if `FALSE` (default), the returned indices are one-based (`1` encodes to first position).

Value

Tensor of insertion indices of same shape as `values`.

op_segment_max *Computes the max of segments in a tensor.*

Description

Computes the max of segments in a tensor.

Usage

```
op_segment_max(data, segment_ids, num_segments = NULL, sorted = FALSE)
```

Arguments

data	Input tensor.
segment_ids	A N-D tensor containing segment indices for each element in data. head(op_shape(data), length(op_shape(segment_ids))) should match op_shape(segment_ids)
num_segments	An integer representing the total number of segments. If not specified, it is inferred from the maximum value in segment_ids.
sorted	A boolean indicating whether segment_ids is sorted. Defaults to FALSE.

Value

A tensor containing the max of segments, where each element represents the max of the corresponding segment in data.

Examples

```
data <- op_convert_to_tensor(c(1, 2, 10, 20, 100, 200))
segment_ids <- op_array(c(1, 1, 2, 2, 3, 3), "int32")
num_segments <- 3
op_segment_max(data, segment_ids, num_segments)

## tf.Tensor([  2.  20. 200.], shape=(3), dtype=float64)

# array([2, 20, 200], dtype=int32)
```

op_segment_sum *Computes the sum of segments in a tensor.*

Description

Computes the sum of segments in a tensor.

Usage

```
op_segment_sum(data, segment_ids, num_segments = NULL, sorted = FALSE)
```

Arguments

data	Input tensor.
segment_ids	A N-D tensor containing segment indices for each element in data. Num dims for segment ids should be strictly smaller or equal to number of dims in data.
num_segments	An integer representing the total number of segments. If not specified, it is inferred from the maximum value in segment_ids.
sorted	A boolean indicating whether segment_ids is sorted. Defaults to FALSE.

Value

A tensor containing the sum of segments, where each element represents the sum of the corresponding segment in data.

Examples

```
data <- op_array(c(1, 2, 10, 20, 100, 200))
segment_ids <- op_array(c(1, 1, 2, 2, 3, 3), "int32")
num_segments <- 3
op_segment_sum(data, segment_ids, num_segments)

## tf.Tensor([  3.  30. 300.], shape=(3), dtype=float32)
```

`op_select` *Return elements from* `choicelist`*, based on conditions in* `condlist`.

Description

Return elements from `choicelist`, based on conditions in `condlist`.

Usage

```
op_select(condlist, choicelist, default = 0L)
```

Arguments

condlist	List of boolean tensors. The list of conditions which determine from which array in choicelist the output elements are taken. When multiple conditions are satisfied, the first one encountered in condlist is used.
choicelist	List of tensors. The list of tensors from which the output elements are taken. This list has to be of the same length as condlist.
default	Optional scalar value. The element inserted in the output when all conditions evaluate to FALSE.

Value

Tensor where the output at position m is the m-th element of the tensor in choicelist where the m-th element of the corresponding tensor in condlist is TRUE.

Examples

```
x <- op_arange(6L)
condlist <- list(x < 3, x > 3)
choicelist <- list(x, x^2)
op_select(condlist, choicelist, 42)

## tf.Tensor([ 1  2 42 16 25 36], shape=(6), dtype=int32)
```

`op_selu` *Scaled Exponential Linear Unit (SELU) activation function.*

Description

It is defined as:
`f(x) =  scale * alpha * (exp(x) - 1.) for x < 0`, `f(x) = scale * x for x >= 0`.

Usage

```
op_selu(x)
```

Arguments

x	Input tensor.

Value

A tensor with the same shape as `x`.

Examples

```
x <- op_array(c(-1, 0, 1))
op_selu(x)
```

```
## tf.Tensor([-1.1113307  0.         1.050701 ], shape=(3), dtype=float32)
```

`op_separable_conv` *General N-D separable convolution.*

Description

This ops supports 1D and 2D separable convolution. `separable_conv` is a depthwise conv followed by a pointwise conv.

Usage

```
op_separable_conv(
```

```
  inputs,
  depthwise_kernel,
  pointwise_kernel,
  strides = 1L,
  padding = "valid",
  data_format = NULL,
  dilation_rate = 1L
)
```

Arguments

inputs	Tensor of rank N+2. inputs has shape (batch_size,) + inputs_spatial_shape + (num_channels,) if data_format="channels_last", or (batch_size, num_channels) + inputs_spatial_shape if data_format="channels_first".
depthwise_kernel	Tensor of rank N+2. depthwise_kernel has shape [kernel_spatial_shape, num_input_channels, r num_input_channels should match the number of channels in inputs.
pointwise_kernel	Tensor of rank N+2. pointwise_kernel has shape (*ones_like(kernel_spatial_shape), num_inpu
strides	int or int tuple/list of len(inputs_spatial_shape), specifying the strides of the convolution along each spatial dimension. If strides is int, then every spatial dimension shares the same strides.
padding	string, either "valid" or "same". "valid" means no padding is applied, and "same" results in padding evenly to the left/right or up/down of the input such that output has the same height/width dimension as the input when strides=1.
data_format	A string, either "channels_last" or "channels_first". data_format determines the ordering of the dimensions in the inputs. If data_format="channels_last", inputs is of shape (batch_size, ..., channels) while if data_format="channels_first", inputs is of shape (batch_size, channels, ...).
dilation_rate	int or int tuple/list of len(inputs_spatial_shape), specifying the dilation rate to use for dilated convolution. If dilation_rate is int, then every spatial dimension shares the same dilation_rate.

Value

A tensor of rank N+2, the result of the depthwise conv operation.

op_shape *Gets the shape of the tensor input.*

Description

Gets the shape of the tensor input.

Usage

```
op_shape(x)
```

Arguments

x	A tensor. This function will try to access the shape attribute of the input tensor.

Value

A list of integers or NULL values, indicating the shape of the input tensor.

Note

On the TensorFlow backend, when `x` is a `tf.Tensor` with dynamic shape, dimensions which are dynamic in the context of a compiled function will have a `tf.Tensor` value instead of a static integer value.

Examples

```
x <- op_zeros(c(8, 12))
op_shape(x)

## shape(8, 12)
```

`op_sigmoid` *Sigmoid activation function.*

Description

It is defined as `f(x) = 1 / (1 + exp(-x))`.

Usage

```
op_sigmoid(x)
```

Arguments

`x`	Input tensor.

Value

A tensor with the same shape as `x`.

Examples

```
x <- op_convert_to_tensor(c(-6, 1, 0, 1, 6))
op_sigmoid(x)
```

```
## tf.Tensor([0.00247262 0.73105858 0.5      0.73105858 0.99752738], shape=(5), dtype=float64)
```

`op_sign` *Returns a tensor with the signs of the elements of* `x`.

Description

Returns a tensor with the signs of the elements of `x`.

Usage

```
op_sign(x)
```

Arguments

`x`	Input tensor.

Value

Output tensor of same shape as `x`.

`op_signbit` *Return the sign bit of the elements of* `x`.

Description

The output boolean tensor contains TRUE where the sign of x is negative, and FALSE otherwise.

Usage

```
op_signbit(x)
```

Arguments

x	Input tensor.

Value

Output boolean tensor of same shape as x.

`op_silu` *Sigmoid Linear Unit (SiLU) activation function, also known as Swish.*

Description

The SiLU activation function is computed by the sigmoid function multiplied by its input. It is defined as `f(x) = x * sigmoid(x)`.

Usage

```
op_silu(x)
```

Arguments

`x`	Input tensor.

Value

A tensor with the same shape as `x`.

Examples

```
x <- op_convert_to_tensor(c(-6, 1, 0, 1, 6))
op_sigmoid(x)
```

```
## tf.Tensor([0.00247262 0.73105858 0.5      0.73105858 0.99752738], shape=(5), dtype=float64)
```

```
op_silu(x)
```

```
## tf.Tensor([-0.01483574  0.73105858  0.       0.73105858  5.98516426], shape=(5), dtype=float64)
```

`op_sin` *Trigonometric sine, element-wise.*

Description

Trigonometric sine, element-wise.

Usage

```
op_sin(x)
```

Arguments

`x`	Input tensor.

Value

Output tensor of same shape as `x`.

`op_sinh` *Hyperbolic sine, element-wise.*

Description

Hyperbolic sine, element-wise.

Usage

```
op_sinh(x)
```

Arguments

x	Input tensor.

Value

Output tensor of same shape as x.

`op_size` *Return the number of elements in a tensor.*

Description

Return the number of elements in a tensor.

Usage

```
op_size(x)
```

Arguments

x	Input tensor.

Value

Number of elements in `x`.

op_slice *Return a slice of an input tensor.*

Description

At a high level, this operation is an explicit replacement for array slicing e.g. `inputs[start_indices:(start_indices + shape)]`. Unlike slicing via brackets, this operation will accept tensor start indices on all backends, which is useful when indices dynamically computed via other tensor operations.

```
(inputs <- op_arange(5*5) |> op_reshape(c(5, 5)))
```

```
## tf.Tensor(
## [[ 1.  2.  3.  4.  5.]
##  [ 6.  7.  8.  9. 10.]
##  [11. 12. 13. 14. 15.]
```

```
##  [16. 17. 18. 19. 20.]
##  [21. 22. 23. 24. 25.]], shape=(5, 5), dtype=float32)

start_indices <- c(3, 3)
shape <- c(2, 2)
op_slice(inputs, start_indices, shape)

## tf.Tensor(
## [[13. 14.]
##  [18. 19.]], shape=(2, 2), dtype=float32)
```

Usage

```
op_slice(inputs, start_indices, shape)
```

Arguments

inputs	A tensor, the tensor to be sliced.
start_indices	A list of length inputs$ndim, specifying the starting indices for updating.
shape	The full shape of the returned slice.

Value

A tensor, has the same shape and dtype as inputs.

`op_slice_update` *Update an input by slicing in a tensor of updated values.*

Description

At a high level, this operation does `inputs[start_indices: start_indices + updates.shape] = updates`. Assume inputs is a tensor of shape `(D1, D2, ..., Dn)`, `start_indices` must be a list of n integers, specifying the starting indices. `updates` must have the same rank as `inputs`, and the size of each dim must not exceed `Di - start_indices[i]`. For example, if we have 2D inputs `inputs = op_zeros(c(5, 5))`, and we want to update the intersection of last 2 rows and last 2 columns as 1, i.e., `inputs[4:5, 4:5] = op_ones(c(2, 2))`, then we can use the code below:

```
inputs <- op_zeros(c(5, 5))
start_indices <- c(3, 3)
updates <- op_ones(c(2, 2))
op_slice_update(inputs, start_indices, updates)

## tf.Tensor(
## [[0. 0. 0. 0. 0.]
##  [0. 0. 0. 0. 0.]
##  [0. 0. 1. 1. 0.]
##  [0. 0. 1. 1. 0.]
##  [0. 0. 0. 0. 0.]], shape=(5, 5), dtype=float32)
```

Usage

```
op_slice_update(inputs, start_indices, updates)
```

Arguments

inputs	A tensor, the tensor to be updated.
start_indices	A list of length inputs$ndim, specifying the starting indices for updating.
updates	A tensor, the new values to be put to inputs at indices. updates must have the same rank as inputs.

Value

A tensor, has the same shape and dtype as inputs.

`op_slogdet` *Compute the sign and natural logarithm of the determinant of a matrix.*

Description

Compute the sign and natural logarithm of the determinant of a matrix.

Usage

```
op_slogdet(x)
```

Arguments

x	Input matrix. It must 2D and square.

Value

A list: `(sign, logabsdet)`. `sign` is a number representing the sign of the determinant. For a real matrix, this is 1, 0, or -1. For a complex matrix, this is a complex number with absolute value 1 (i.e., it is on the unit circle), or else 0. `logabsdet` is the natural log of the absolute value of the determinant.

op_softmax *Softmax activation function.*

Description

The elements of the output vector lie within the range (0, 1), and their total sum is exactly 1 (excluding the floating point rounding error).

Each vector is processed independently. The axis argument specifies the axis along which the function is applied within the input.

It is defined as: f(x) = exp(x) / sum(exp(x))

Usage

```
op_softmax(x, axis = -1L)
```

Arguments

x	Input tensor.
axis	Integer, axis along which the softmax is applied.

Value

A tensor with the same shape as x.

Examples

```
x <- op_array(c(-1, 0, 1))
op_softmax(x)

## tf.Tensor([0.09003057 0.24472848 0.66524094], shape=(3), dtype=float32)
```

`op_softplus` *Softplus activation function.*

Description

It is defined as `f(x) = log(exp(x) + 1)`, where `log` is the natural logarithm and `exp` is the exponential function.

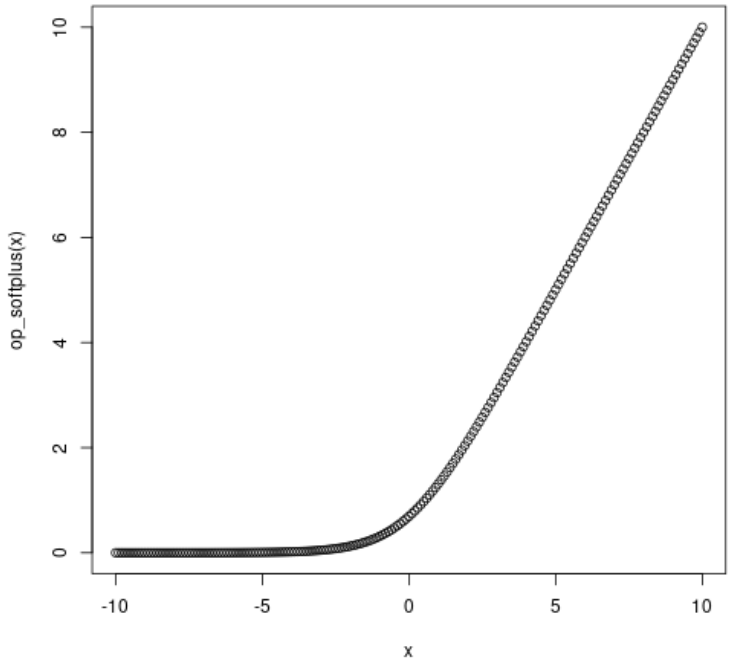
Usage

```
op_softplus(x)
```

Arguments

`x`	Input tensor.

Value



A tensor with the same shape as `x`.

Examples

```
x <- op_convert_to_tensor(c(-0.555, 0, 0.555))
op_softplus(x)
```

```
## tf.Tensor([0.45366606 0.69314718 1.00866606], shape=(3), dtype=float64)
```

```
x <- seq(-10, 10, .1)
plot(x, op_softplus(x))
```

`op_softsign` *Softsign activation function.*

Description

It is defined as `f(x) = x / (abs(x) + 1)`.

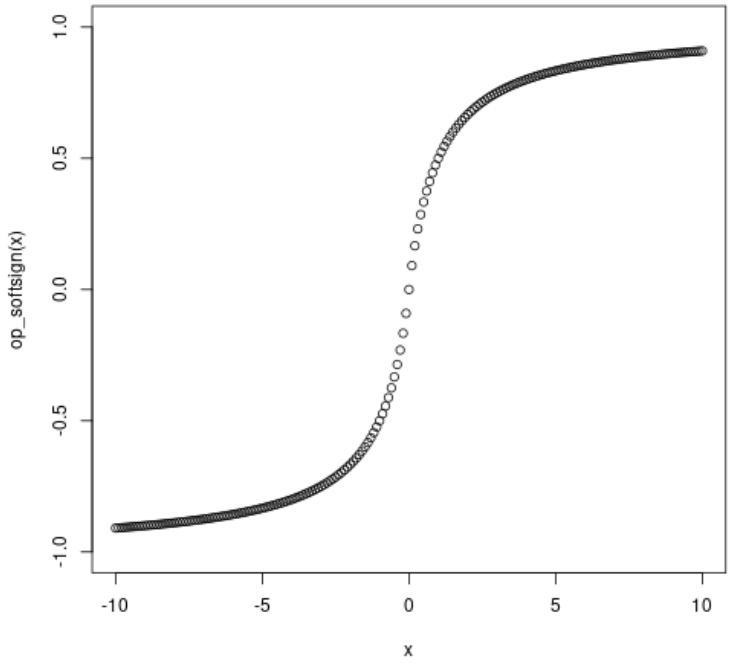
Usage

```
op_softsign(x)
```

Arguments

`x`	Input tensor.

Value



A tensor with the same shape as `x`.

Examples

```
x <- op_convert_to_tensor(c(-0.100, -10.0, 1.0, 0.0, 100.0))
op_softsign(x)
```

```
## tf.Tensor([-0.09090909 -0.90909091  0.5       0.        0.99009901], shape=(5), dtype=float64)
```

```
x <- seq(-10, 10, .1)
plot(x, op_softsign(x), ylim = c(-1, 1))
```

op_soft_shrink *Soft Shrink activation function.*

Description

It is defined as

`f(x) = x - threshold` if `x > threshold`, `f(x) = x + threshold` if `x < -threshold`, `f(x) = 0` otherwise.

Usage

```
op_soft_shrink(x, threshold = 0.5)
```

Arguments

x	Input tensor.
threshold	Threshold value. Defaults to 0.5.

Value

A tensor with the same shape as `x`.

Examples

```
x <- op_array(c(-1, 0, 1))
op_soft_shrink(x)

## tf.Tensor([-0.5  0.   0.5], shape=(3), dtype=float32)
```

`op_solve` *Solves a linear system of equations given by* `a x = b`.

Description

Solves for `x` in the equation `a %*% x == b`.

Usage

```
op_solve(a, b)
```

Arguments

`a`	A tensor of shape `(..., M, M)` representing the coefficients matrix.
`b`	A tensor of shape `(..., M)` or `(..., M, N)` representing the right-hand side or "dependent variable" matrix.

Value

A tensor of shape `(..., M)` or `(..., M, N)` representing the solution of the linear system. Returned shape is identical to `b`.

Examples

```
a <- op_array(c(1, 2, 4, 5), dtype="float32") |> op_reshape(c(2, 2))
b <- op_array(c(2, 4, 8, 10), dtype="float32") |> op_reshape(c(2, 2))
op_solve(a, b)
```

```
## tf.Tensor(
## [[2. 0.]
##  [0. 2.]], shape=(2, 2), dtype=float32)
```

op_solve_triangular *Solves a linear system of equations given by* a %*% x = b.

Description

Solves a linear system of equations given by a %*% x = b.

Usage

```
op_solve_triangular(a, b, lower = FALSE)
```

Arguments

a	A tensor of shape (..., M, M) representing the coefficients matrix.
b	A tensor of shape (..., M) or (..., M, N) representing the right-hand side or "dependent variable" matrix.
lower	logical. Use only data contained in the lower triangle of a. Default is to use upper triangle.

Value

A tensor of shape (..., M) or (..., M, N) representing the solution of the linear system. Returned shape is identical to b.

`op_sort` *Sorts the elements of* `x` *along a given axis in ascending order.*

Description

Sorts the elements of `x` along a given axis in ascending order.

Usage

```
op_sort(x, axis = -1L)
```

Arguments

`x`	Input tensor.
`axis`	Axis along which to sort. If `NULL`, the tensor is flattened before sorting. Defaults to `-1`; the last axis.

Value

Sorted tensor.

`op_sparsemax` *Sparsemax activation function.*

Description

For each batch `i`, and class `j`, sparsemax activation function is defined as:
`sparsemax(x)[i, j] = max(x[i, j] - (x[i, :]), 0)`.

Usage

```
op_sparsemax(x, axis = -1L)
```

Arguments

x	Input tensor.
axis	int, axis along which the sparsemax operation is applied.

Value

A tensor, output of sparsemax transformation. Has the same type and shape as x.

Examples

```
x <- op_array(c(-1., 0., 1.))
op_sparsemax(x)

## tf.Tensor([0. 0. 1.], shape=(3), dtype=float32)
```

`op_sparse_categorical_crossentropy` *Computes sparse categorical cross-entropy loss.*

Description

The sparse categorical cross-entropy loss is similar to categorical cross-entropy, but it is used when the target tensor contains integer class labels instead of one-hot encoded vectors. It measures the dissimilarity between the target and output probabilities or logits.

Usage

```
op_sparse_categorical_crossentropy(
  target,
  output,
  from_logits = FALSE,
  axis = -1L
)
```

Arguments

`target`	The target tensor representing the true class labels as integers. Its shape should match the shape of the `output` tensor except for the last dimension.
`output`	The output tensor representing the predicted probabilities or logits. Its shape should match the shape of the `target` tensor except for the last dimension.
`from_logits`	(optional) Whether `output` is a tensor of logits or probabilities. Set it to `TRUE` if `output` represents logits; otherwise, set it to `FALSE` if `output` represents probabilities. Defaults to `FALSE`.
`axis`	(optional) The axis along which the sparse categorical cross-entropy is computed. Defaults to `-1`, which corresponds to the last dimension of the tensors.

Value

Integer tensor: The computed sparse categorical cross-entropy loss between `target` and `output`.

Examples

```
target <- op_array(c(0, 1, 2), dtype="int32")
output <- op_array(rbind(c(0.9, 0.05, 0.05),
                         c(0.1, 0.8,  0.1),
                         c(0.2, 0.3,  0.5)))
op_sparse_categorical_crossentropy(target, output)

## tf.Tensor([0.10536052 0.22314355 0.69314718], shape=(3), dtype=float64)

`op_sparse_plus` *SparsePlus activation function.*

Description

It is defined as

`f(x) = 0` for `x <= -1`. `f(x) = (1/4) * (x + 1)^2` for `-1 < x < 1`. `f(x) = x` for `x >= 1`.

Usage

```
op_sparse_plus(x)
```

Arguments

x	Input tensor.

Value

A tensor with the same shape as `x`.

Examples

```
x <- op_array(c(-1.0, 0.0, 1.0))
op_sparse_plus(x)

## tf.Tensor([0.   0.25 1.  ], shape=(3), dtype=float32)
```

`op_split` *Split a tensor into chunks.*

Description

Split a tensor into chunks.

Usage

```
op_split(x, indices_or_sections, axis = 1L)
```

Arguments

x	Input tensor.
indices_or_sections	If an integer, N, the tensor will be split into N equal sections along axis. If a 1-D array of sorted integers, the entries indicate indices at which the tensor will be split along axis.
axis	Axis along which to split. Defaults to 1, the first axis.

Value

A list of tensors.

Note

A split does not have to result in equal division when using Torch backend.

Example

```
x <- op_arange(12)

# pass a scalar integer for n sections
op_split(x, 2)

## [[1]]
## tf.Tensor([1. 2. 3. 4. 5. 6.], shape=(6), dtype=float32)
##
## [[2]]
## tf.Tensor([ 7.  8.  9. 10. 11. 12.], shape=(6), dtype=float32)

op_split(x, 3)

## [[1]]
## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)
##
## [[2]]
## tf.Tensor([5. 6. 7. 8.], shape=(4), dtype=float32)
##
## [[3]]
## tf.Tensor([ 9. 10. 11. 12.], shape=(4), dtype=float32)

# 1-d array/tensor for indices
op_split(x, array(c(3, 8)))

## [[1]]
## tf.Tensor([1. 2.], shape=(2), dtype=float32)
##
```

```
## [[2]]
## tf.Tensor([3. 4. 5. 6. 7.], shape=(5), dtype=float32)
##
## [[3]]
## tf.Tensor([ 8.  9. 10. 11. 12.], shape=(5), dtype=float32)

op_split(x, array(c(3)))

## [[1]]
## tf.Tensor([1. 2.], shape=(2), dtype=float32)

`op_sqrt` *Return the non-negative square root of a tensor, element-wise.*

Description

Return the non-negative square root of a tensor, element-wise.

Usage

```
op_sqrt(x)
```

Arguments

x	Input tensor.

Value

Output tensor, the non-negative square root of `x`.

op_squareplus *Squareplus activation function.*

Description

The Squareplus activation function is defined as:

`f(x) = (x + sqrt(x^2 + b)) / 2`

Usage

```
op_squareplus(x, b = 4L)
```

Arguments

x	Input tensor.
b	Smoothness parameter. Defaults to 4.

Value

A tensor with the same shape as `x`.

Examples

```
x <- op_array(c(-1.0, 0.0, 1.0))
op_squareplus(x)
```

```
## tf.Tensor([0.618034 1.       1.618034], shape=(3), dtype=float32)
```

op_squeeze *Remove axes of length one from* x.

Description

Remove axes of length one from x.

Usage

```
op_squeeze(x, axis = NULL)
```

Arguments

x	Input tensor.
axis	Select a subset of the entries of length one in the shape.

Value

The input tensor with all or a subset of the dimensions of length 1 removed.

`op_stack` *Join a sequence of tensors along a new axis.*

Description

The `axis` parameter specifies the index of the new axis in the dimensions of the result.

Usage

```
op_stack(x, axis = 1L)
```

Arguments

`x`	A sequence of tensors.
`axis`	Axis along which to stack. Defaults to 1, the first axis.

Value

The stacked tensor.

`op_std` *Compute the standard deviation along the specified axis.*

Description

Compute the standard deviation along the specified axis.

Usage

```
op_std(x, axis = NULL, keepdims = FALSE)
```

Arguments

x	Input tensor.
axis	Axis along which to compute standard deviation. Default is to compute the standard deviation of the flattened tensor.
keepdims	If this is set to TRUE, the axes which are reduced are left in the result as dimensions with size one.

Value

Output tensor containing the standard deviation values.

`op_stft` *Short-Time Fourier Transform along the last axis of the input.*

Description

The STFT computes the Fourier transform of short overlapping windows of the input. This giving frequency components of the signal as they change over time.

Usage

```
op_stft(
  x,
  sequence_length,
  sequence_stride,
  fft_length,
  window = "hann",
  center = TRUE
)
```

Arguments

`x`	Input tensor.
`sequence_length`	An integer representing the sequence length.
`sequence_stride`	An integer representing the sequence hop size.
`fft_length`	An integer representing the size of the FFT to apply. If not specified, uses the smallest power of 2 enclosing `sequence_length`.

window	A string, a tensor of the window or NULL. If window is a string, available values are "hann" and "hamming". If window is a tensor, it will be used directly as the window and its length must be sequence_length. If window is NULL, no windowing is used. Defaults to "hann".
center	Whether to pad x on both sides so that the t-th sequence is centered at time t * sequence_stride. Otherwise, the t-th sequence begins at time t * sequence_stride. Defaults to TRUE.

Value

A list containing two tensors - the real and imaginary parts of the STFT output.

Examples

```
x <- op_array(c(0, 1, 2, 3, 4))
op_stft(x, 3, 2, 3)
```

```
## [[1]]
## tf.Tensor(
## [[ 0.  0.]
##  [ 2. -1.]
##  [ 4. -2.]], shape=(3, 2), dtype=float32)
##
## [[2]]
## tf.Tensor(
## [[ 0.         0.       ]
##  [ 0.        -1.7320508]
##  [ 0.        -3.4641016]], shape=(3, 2), dtype=float32)
```

`op_stop_gradient` *Stops gradient computation.*

Description

Stops gradient computation.

Usage

```
op_stop_gradient(variable)
```

Arguments

`variable`	A tensor variable for which the gradient computation is to be disabled.

Value

The variable with gradient computation disabled.

Examples

```
var <- op_convert_to_tensor(c(1, 2, 3), dtype="float32")
var <- op_stop_gradient(var)
```

`op_subset` *Subset elements from a tensor*

Description

Extract elements from a tensor using common R-style `[` indexing idioms. This function can also be conveniently accessed via the syntax `tensor@r[...]`.

Usage

```
op_subset(x, ...)

op_subset(x, ...) <- value

op_subset_set(x, ..., value)
```

Arguments

`x`	Input tensor.
`...`	Indices specifying elements to extract. Each argument in `...` can be: • An integer scalar • A 1-d integer or logical vector • `NULL` or `newaxis` • The `..` symbol • A slice expression using `:` If only a single argument is supplied to `...`, then `..1` can also be: • A logical array with the same shape as `x` • An integer matrix where `ncol(..1) == op_rank(x)`
`value`	new value to replace the selected subset with.

Details

While the semantics are similar to R's `[`, there are some differences:

Value

A tensor containing the subset of elements.

Differences from R's `[`:

- Negative indices follow Python-style indexing, counting from the end of the array.
- `NULL` or `newaxis` adds a new dimension (equivalent to `op_expand_dims()`).
- If fewer indices than dimensions (`op_rank(x)`) are provided, missing dimensions are implicitly filled. For example, if `x` is a matrix, `x[1]` returns the first row.
- `..` or `all_dims()` expands to include all unspecified dimensions (see examples).
- Extended slicing syntax (`:`) is supported, including:
  - Strided steps: `x@r[start:end:step]`
  - `NA` values for `start` and `end`. `NA` for `start` defaults to `1`, and `NA` for `end` defaults to the axis size.
- A logical array matching the shape of `x` selects elements in row-wise order.

Similarities with R's `[`:

Similarities to R's `[` (differences from Python's `[`):

- Positive indices are 1-based.
- Slices (`x[start:end]`) are inclusive of `end`.
- 1-d logical/integer arrays subset along their respective axis. Multiple vectors provided for different axes return intersected subsets.
- A single integer matrix with `ncol(i) == op_rank(x)` selects elements by coordinates. Each row in the matrix specifies the location of one value, where each column corresponds to an axis in the tensor being subsetted. This means you use a 2-column matrix to subset a matrix, a 3-column matrix to subset a 3d array, and so on.

Examples

```
(x <- op_arange(5L) + 10L)

## tf.Tensor([11 12 13 14 15], shape=(5), dtype=int32)

# Basic example, get first element
op_subset(x, 1)

## tf.Tensor(11, shape=(), dtype=int32)
```

```
# Use `@r[` syntax
x@r[1]           # same as `op_subset(x, 1)`

## tf.Tensor(11, shape=(), dtype=int32)

x@r[1:2]         # get the first 2 elements

## tf.Tensor([11 12], shape=(2), dtype=int32)

x@r[c(1, 3)]     # first and third element

## tf.Tensor([11 13], shape=(2), dtype=int32)

# Negative indices
x@r[-1]          # last element

## tf.Tensor(15, shape=(), dtype=int32)

x@r[-2]          # second to last element

## tf.Tensor(14, shape=(), dtype=int32)

x@r[c(-1, -2)]   # last and second to last elements

## tf.Tensor([15 14], shape=(2), dtype=int32)

x@r[c(-2, -1)]   # second to last and last elements

## tf.Tensor([14 15], shape=(2), dtype=int32)

x@r[c(1, -1)]    # first and last elements

## tf.Tensor([11 15], shape=(2), dtype=int32)

# Slices
x@r[1:3]          # first 3 elements

## tf.Tensor([11 12 13], shape=(3), dtype=int32)
```

```
x@r[NA:3]         # first 3 elements

## tf.Tensor([11 12 13], shape=(3), dtype=int32)

x@r[1:5]          # all elements

## tf.Tensor([11 12 13 14 15], shape=(5), dtype=int32)

x@r[1:-1]         # all elements

## tf.Tensor([11 12 13 14 15], shape=(5), dtype=int32)

x@r[NA:NA]        # all elements

## tf.Tensor([11 12 13 14 15], shape=(5), dtype=int32)

x@r[]             # all elements

## tf.Tensor([11 12 13 14 15], shape=(5), dtype=int32)

x@r[1:-2]         # drop last element

## tf.Tensor([11 12 13 14], shape=(4), dtype=int32)

x@r[NA:-2]        # drop last element

## tf.Tensor([11 12 13 14], shape=(4), dtype=int32)

x@r[2:NA]         # drop first element

## tf.Tensor([12 13 14 15], shape=(4), dtype=int32)

# 2D array examples
xr <- array(1:12, c(3, 4))
x <- op_convert_to_tensor(xr)

# Basic subsetting
x@r[1, ]      # first row
```

```
## tf.Tensor([ 1  4  7 10], shape=(4), dtype=int32)

x@r[1]        # also first row! Missing axes are implicitly inserted

## tf.Tensor([ 1  4  7 10], shape=(4), dtype=int32)

x@r[-1]       # last row

## tf.Tensor([ 3  6  9 12], shape=(4), dtype=int32)

x@r[, 2]      # second column

## tf.Tensor([4 5 6], shape=(3), dtype=int32)

x@r[, 2:2]    # second column, but shape preserved (like [, drop=FALSE])

## tf.Tensor(
## [[4]
##  [5]
##  [6]], shape=(3, 1), dtype=int32)

# Subsetting with a boolean array
# Note: extracted elements are selected row-wise, not column-wise
mask <- x >= 6
x@r[mask]             # returns a 1D tensor

## tf.Tensor([ 7 10  8 11  6  9 12], shape=(7), dtype=int32)

x.r <- as.array(x)
mask.r <- as.array(mask)
# as.array(x)[mask] selects column-wise. Use `aperm()` to reverse search order.
all(aperm(x.r)[aperm(mask.r)] == as.array(x@r[mask]))

## [1] TRUE

# Subsetting with a matrix of index positions
indices <- rbind(c(1, 1), c(2, 2), c(3, 3))
x@r[indices] # get diagonal elements

## tf.Tensor([1 5 9], shape=(3), dtype=int32)
```

```
x.r[indices] # same as subsetting an R array

## [1] 1 5 9

# 3D array examples
# Image: 4x4 pixels, 3 colors (RGB)
# Tensor shape: (img_height, img_width, img_color_channels)
shp <- shape(4, 4, 3)

`op_subtract` *Subtract arguments element-wise.*

Description

Note that this function is automatically called when using the R operator `-` with a tensor.

```
x <- op_ones(c(3))
op_subtract(x, x)

## tf.Tensor([0. 0. 0.], shape=(3), dtype=float32)
```

```
x - x
```

```
## tf.Tensor([0. 0. 0.], shape=(3), dtype=float32)
```

Usage

```
op_subtract(x1, x2)
```

Arguments

x1	First input tensor.
x2	Second input tensor.

Value

Output tensor, element-wise difference of x1 and x2.

op_sum *Sum of a tensor over the given axes.*

Description

Sum of a tensor over the given axes.

Usage

```
op_sum(x, axis = NULL, keepdims = FALSE)
```

Arguments

x	Input tensor.
axis	Axis or axes along which the sum is computed. The default is to compute the sum of the flattened tensor.
keepdims	If this is set to TRUE, the axes which are reduced are left in the result as dimensions with size one.

Value

Output tensor containing the sum.

op_svd *Computes the singular value decomposition of a matrix.*

Description

Computes the singular value decomposition of a matrix.

Usage

```
op_svd(x, full_matrices = TRUE, compute_uv = TRUE)
```

Arguments

x	Input tensor of shape (..., M, N).
full_matrices	Logical
compute_uv	Logical

Value

A list of three tensors:

- a tensor of shape (..., M, M) containing the left singular vectors,
- a tensor of shape (..., M, N) containing the singular values and
- a tensor of shape (..., N, N) containing the right singular vectors.

op_swapaxes *Interchange two axes of a tensor.*

Description

Interchange two axes of a tensor.

Usage

```
op_swapaxes(x, axis1, axis2)
```

Arguments

x	Input tensor.
axis1	First axis.
axis2	Second axis.

Value

A tensor with the axes swapped.

`op_switch` *Apply exactly one of the* `branches` *given by* `index`.

Description

If `index` is out of bounds, it is clamped to within bounds.

The semantics of `switch` are given roughly by this implementation:

```
op_switch <- function(index, branches, ...) {
  index <- op_clip(index, 1, length(branches))
  branches[[index]](...)
}
```

Usage

```
op_switch(index, branches, ...)
```

Arguments

index	An integer scalar indicating which branch function to apply (1-based).
branches	A list of functions to be applied based on index.
...	Inputs to whichever branch is applied.

Value

The outputs of branch(...) for the branch that was selected based on index.

Examples

```
add_fn <- function(x, y) x + y + 100
subtract_fn <- function(x, y) x - y - 100
x <- op_array(2)
y <- op_array(0.5)
branches <- list(add_fn, subtract_fn)
op_switch(0, branches, x, y) # +

## tf.Tensor(102.5, shape=(), dtype=float32)

op_switch(1, branches, x, y) # +

## tf.Tensor(102.5, shape=(), dtype=float32)

op_switch(2, branches, x, y) # -

## tf.Tensor(-98.5, shape=(), dtype=float32)

op_switch(3, branches, x, y) # -

## tf.Tensor(-98.5, shape=(), dtype=float32)
```

op_take *Take elements from a tensor along an axis.*

Description

Take elements from a tensor along an axis.

Usage

```
op_take(x, indices, axis = NULL, zero_indexed = FALSE)
```

Arguments

x	Source tensor.
indices	The indices of the values to extract.
axis	The axis over which to select values. By default, the flattened input tensor is used.
zero_indexed	If TRUE, treats indices as zero-based (0 encodes to first position); if FALSE (default), treats indices as one-based (1 encodes to first position).

Value

The corresponding tensor of values.

`op_take_along_axis` *Select values from* `x` *at the 1-D* `indices` *along the given axis.*

Description

Select values from `x` at the 1-D `indices` along the given axis.

Usage

```
op_take_along_axis(x, indices, axis = NULL, zero_indexed = FALSE)
```

Arguments

`x`	Source tensor.
`indices`	The indices of the values to extract.
`axis`	The axis over which to select values. By default, the flattened input tensor is used.
`zero_indexed`	If `TRUE`, treats indices as zero-based (`0` encodes to first position); if `FALSE` (default), treats indices as one-based (`1` encodes to first position).

Value

The corresponding tensor of values.

op_tan *Compute tangent, element-wise.*

Description

Compute tangent, element-wise.

Usage

```
op_tan(x)
```

Arguments

x	Input tensor.

Value

Output tensor of same shape as x.

op_tanh *Hyperbolic tangent, element-wise.*

Description

Hyperbolic tangent, element-wise.

Usage

```
op_tanh(x)
```

Arguments

x	Input tensor.

Value

Output tensor of same shape as `x`.

`op_tanh_shrink` *Applies the tanh shrink function element-wise.*

Description

It is defined as:

`f(x) = x - tanh(x)`.

Usage

```
op_tanh_shrink(x)
```

Arguments

`x`	Input tensor.

Value

Output tensor of the same shape as `x`, where each element is transformed according to the tanh shrink operation.

Examples

```
x <- op_array(c(-1., 0., 1.))
op_tanh_shrink(x)
```

```
## tf.Tensor([-0.23840582  0.          0.23840582], shape=(3), dtype=float32)
```

`op_tensordot` *Compute the tensor dot product along specified axes.*

Description

Compute the tensor dot product along specified axes.

Usage

```
op_tensordot(x1, x2, axes = 3L)
```

Arguments

x1	First tensor.
x2	Second tensor.
axes	• If an integer, N, sum over the last N axes of x1 and the first N axes of x2 in order. The sizes of the corresponding axes must match. • Or, a list of axes to be summed over, first sequence applying to x1, second to x2. Both sequences must be of the same length.

Value

The tensor dot product of the inputs.

`op_threshold` *Threshold activation function.*

Description

The function thresholds the input `x` as follows: `f(x)` = `x` if `x` > `threshold`, `f(x)` = `default_value` otherwise.

Usage

```
op_threshold(x, threshold, default_value)
```

Arguments

`x`	Input tensor.
`threshold`	The value that decides when to retain or replace `x`.
`default_value`	Value to assign when `x` <= `threshold`.

Value

A tensor with the same shape as `x`.

Examples

```
x <- op_array(c(-1.0, 0.0, 1.0, 2.0))
op_threshold(x, 1, 0)

## tf.Tensor([0. 0. 0. 2.], shape=(4), dtype=float32)
```

`op_tile` *Repeat* `x` *the number of times given by* `repeats`.

Description

If `repeats` has length `d`, the result will have dimension of `max(d, x.ndim)`.

If `x.ndim < d`, `x` is promoted to be d-dimensional by prepending new axes.

If `x.ndim > d`, `repeats` is promoted to `x.ndim` by prepending 1's to it.

Usage

```
op_tile(x, repeats)
```

Arguments

`x`	Input tensor.
`repeats`	The number of repetitions of `x` along each axis.

Value

The tiled output tensor.

op_top_k *Finds the top-k values and their indices in a tensor.*

Description

Finds the top-k values and their indices in a tensor.

Usage

```
op_top_k(x, k, sorted = TRUE, zero_indexed = FALSE)
```

Arguments

x	Input tensor.
k	An integer representing the number of top elements to retrieve.
sorted	A boolean indicating whether to sort the output in descending order. Defaults to TRUE.
zero_indexed	If TRUE, the returned indices are zero-based (0 encodes to first position); if FALSE (default), the returned indices are one-based (1 encodes to first position).

Value

A list containing two tensors. The first tensor contains the top-k values, and the second tensor contains the indices of the top-k values in the input tensor.

Examples

```
x <- op_array(c(5, 2, 7, 1, 9, 3), "int32")
op_top_k(x, k = 3)

## $values
## tf.Tensor([9 7 5], shape=(3), dtype=int32)
##
## $indices
## tf.Tensor([5 3 1], shape=(3), dtype=int32)

c(values, indices) %<-% op_top_k(x, k = 3)
values

## tf.Tensor([9 7 5], shape=(3), dtype=int32)

indices

## tf.Tensor([5 3 1], shape=(3), dtype=int32)
```

op_trace *Return the sum along diagonals of the tensor.*

Description

If x is 2-D, the sum along its diagonal with the given offset is returned, i.e., the sum of elements x[i, i+offset] for all i.

If a has more than two dimensions, then the axes specified by axis1 and axis2 are used to determine the 2-D sub-arrays whose traces are returned.

The shape of the resulting tensor is the same as that of x with axis1 and axis2 removed.

Usage

```
op_trace(x, offset = 0L, axis1 = 1L, axis2 = 2L)
```

Arguments

x	Input tensor.
offset	Offset of the diagonal from the main diagonal. Can be both positive and negative. Defaults to 0.
axis1	Axis to be used as the first axis of the 2-D sub-arrays. Defaults to 1. (first axis).
axis2	Axis to be used as the second axis of the 2-D sub-arrays. Defaults to 2. (second axis).

Value

If x is 2-D, the sum of the diagonal is returned. If x has larger dimensions, then a tensor of sums along diagonals is returned.

`op_transpose` *Returns a tensor with* `axes` *transposed.*

Description

Returns a tensor with `axes` transposed.

Usage

```
op_transpose(x, axes = NULL)
```

Arguments

`x`	Input tensor.
`axes`	Sequence of integers. Permutation of the dimensions of `x`. By default, the order of the axes are reversed.

Value

x with its axes permuted.

op_tri *Return a tensor with ones at and below a diagonal and zeros elsewhere.*

Description

Return a tensor with ones at and below a diagonal and zeros elsewhere.

Usage

```
op_tri(N, M = NULL, k = 0L, dtype = NULL)
```

Arguments

N	Number of rows in the tensor.
M	Number of columns in the tensor.
k	The sub-diagonal at and below which the array is filled. k = 0 is the main diagonal, while k < 0 is below it, and k > 0 is above. The default is 0.
dtype	Data type of the returned tensor. The default is "float32".

Value

Tensor with its lower triangle filled with ones and zeros elsewhere. T[i, j] == 1 for j <= i + k, 0 otherwise.

`op_tril` *Return lower triangle of a tensor.*

Description

For tensors with `ndim` exceeding 2, `tril` will apply to the final two axes.

Usage

```
op_tril(x, k = 0L)
```

Arguments

`x`	Input tensor.
`k`	Diagonal above which to zero elements. Defaults to `0`. the main diagonal. `k < 0` is below it, and `k > 0` is above it.

Value

Lower triangle of `x`, of same shape and data type as `x`.

op_trunc *Return the truncated value of the input, element-wise.*

Description

The truncated value of the scalar x is the nearest integer i which is closer to zero than x is. In short, the fractional part of the signed number x is discarded.

Usage

```
op_trunc(x)
```

Arguments

x	Input tensor.

Value

The truncated value of each element in x.

Examples

```
x <- op_array(c(-1.7, -1.5, -0.2, 0.2, 1.5, 1.7, 2.0))
op_trunc(x)
```

```
## tf.Tensor([-1. -1. -0.  0.  1.  1.  2.], shape=(7), dtype=float32)
```

op_unravel_index *Convert flat indices to coordinate arrays in a given array shape.*

Description

Convert flat indices to coordinate arrays in a given array shape.

Usage

```
op_unravel_index(indices, shape)
```

Arguments

indices	An integer or array of integers representing flat indices.
shape	The shape of the array to unravel into.

Value

Tuple of arrays for each dimension with unraveled indices.

Examples

```
indices <- c(1, 5)
shape <- array(c(3, 3))
op_unravel_index(indices, shape)

## [[1]]
## tf.Tensor([0 1], shape=(2), dtype=int32)
##
## [[2]]
## tf.Tensor([0 1], shape=(2), dtype=int32)
```

op_unstack *Unpacks the given dimension of a rank-R tensor into rank-(R-1) tensors.*

Description

Unpacks the given dimension of a rank-R tensor into rank-(R-1) tensors.

Usage

```
op_unstack(x, num = NULL, axis = 1L)
```

Arguments

x	The input tensor.
num	The length of the dimension axis. Automatically inferred if NULL.
axis	The axis along which to unpack.

Value

A list of tensors unpacked along the given axis.

Examples

```
x <- op_array(rbind(c(1, 2),
                    c(3, 4)))
op_unstack(x, axis=1)

## [[1]]
## tf.Tensor([1. 2.], shape=(2), dtype=float64)
##
## [[2]]
## tf.Tensor([3. 4.], shape=(2), dtype=float64)

op_unstack(x, axis=2)
```

```
## [[1]]
## tf.Tensor([1. 3.], shape=(2), dtype=float64)
##
## [[2]]
## tf.Tensor([2. 4.], shape=(2), dtype=float64)

all.equal(op_unstack(x),
          op_unstack(x, axis = 1))

## [1] TRUE

all.equal(op_unstack(x, axis = -1),
          op_unstack(x, axis = 2))

## [1] TRUE

# [array([1, 2)), array([3, 4))]
```

[3, 4))]: R:3,%204))

`op_var` *Compute the variance along the specified axes.*

Description

Compute the variance along the specified axes.

Usage

```
op_var(x, axis = NULL, keepdims = FALSE)
```

Arguments

`x`	Input tensor.
`axis`	Axis or axes along which the variance is computed. The default is to compute the variance of the flattened tensor.
`keepdims`	If this is set to `TRUE`, the axes which are reduced are left in the result as dimensions with size one.

Value

Output tensor containing the variance.

op_vdot *Return the dot product of two vectors.*

Description

If the first argument is complex, the complex conjugate of the first argument is used for the calculation of the dot product.

Multidimensional tensors are flattened before the dot product is taken.

Usage

```
op_vdot(x1, x2)
```

Arguments

x1	First input tensor. If complex, its complex conjugate is taken before calculation of the dot product.
x2	Second input tensor.

Value

Output tensor.

`op_vectorize` *Turn a function into a vectorized function.*

Description

Turn a function into a vectorized function.

Usage

```
op_vectorize(func, ..., excluded = NULL, signature = NULL)
```

Arguments

`func`	Callable of a single tensor argument.
`...`	For forward/backward compatability.
`excluded`	Optional set of integers representing positional arguments for which the function will not be vectorized. These will be passed directly to `func` unmodified.
`signature`	Optional generalized universal function signature, e.g., `"(m,n),(n)->(m)"` for vectorized matrix-vector multiplication. If provided, `func` will be called with (and expected to return) arrays with shapes given by the size of corresponding core dimensions. By default, `func` is assumed to take scalar tensors as input and output.

Value

A new function that applies `func` to every element of its input along axis 1 (the batch axis, the first axis).

Examples

```
# currently does not work w/ tensorflow backend
if(config_backend() != "tensorflow") {

  myfunc <- function(a, b) a + b

  vfunc <- op_vectorize(myfunc)
  y <- vfunc(c(1, 2, 3, 4), 2)
  print(y)
  # with Jax backend, y is:
  # Array([3., 4., 5., 6.], dtype=float32)
}
```

`op_vectorized_map` *Parallel map of function* `f` *on the first axis of tensor(s)* `elements`.

Description

Schematically, `op_vectorized_map()` maps over the first dimension of the provided tensors. If `elements` is a list of tensors, then each of the tensors are required to have the same size first dimension, and they are iterated over together.

Usage

```
op_vectorized_map(elements, f)
```

Arguments

`elements`	see description
`f`	A function taking either a tensor, or list of tensors.

Value

A tensor or list of tensors, the result of mapping `f` across `elements`.

Examples

```
(x <- op_arange(12L) |> op_reshape(c(3, 4)))
```

```
## tf.Tensor(
## [[ 1  2  3  4]
##  [ 5  6  7  8]
##  [ 9 10 11 12]], shape=(3, 4), dtype=int32)
```

```
x |> op_vectorized_map(\(row) {row + 10})

## tf.Tensor(
## [[11 12 13 14]
##  [15 16 17 18]
##  [19 20 21 22]], shape=(3, 4), dtype=int32)

list(x, x, x) |> op_vectorized_map(\(rows) Reduce(`+`, rows))

## tf.Tensor(
## [[ 3  6  9 12]
##  [15 18 21 24]
##  [27 30 33 36]], shape=(3, 4), dtype=int32)
```

Note that f may be traced and compiled. Meaning, the R function may only evaluated once with symbolic tensors if using Jax or TensorFlow backends, and not with eager tensors. See the output from str() in these examples:

```
# simplest case, map f over rows of x,
# where .x is 1 row of x
input <- x
output <- op_vectorized_map(input, function(.x) {
  str(.x)
  .x + 10
})

## <tf.Tensor 'loop_body/GatherV2:0' shape=(4) dtype=int32>

output

## tf.Tensor(
## [[11 12 13 14]
##  [15 16 17 18]
##  [19 20 21 22]], shape=(3, 4), dtype=int32)

# map f over two tensors simultaneously. Here, # `.x` is a list of two
# tensors. The return values from each call of `f(row)` are stacked to form the
# final output
input <- list(x, x)
output <- op_vectorized_map(input, function(.x) {
  str(.x)
  .x[[1]] + 10
})
```

```
## List of 2
##  $ :<tf.Tensor 'loop_body/GatherV2:0' shape=(4) dtype=int32>
##  $ :<tf.Tensor 'loop_body/GatherV2_1:0' shape=(4) dtype=int32>

output

## tf.Tensor(
## [[11 12 13 14]
##  [15 16 17 18]
##  [19 20 21 22]], shape=(3, 4), dtype=int32)

# same as above, but now returning two tensors in the final output
output <- op_vectorized_map(input, function(.x) {
  str(.x)
  c(.x1, .x2) %<-% .x
  list(.x1+10, .x2+20)
})

## List of 2
##  $ :<tf.Tensor 'loop_body/GatherV2:0' shape=(4) dtype=int32>
##  $ :<tf.Tensor 'loop_body/GatherV2_1:0' shape=(4) dtype=int32>

output

## [[1]]
## tf.Tensor(
## [[11 12 13 14]
##  [15 16 17 18]
##  [19 20 21 22]], shape=(3, 4), dtype=int32)
##
## [[2]]
## tf.Tensor(
## [[21 22 23 24]
##  [25 26 27 28]
##  [29 30 31 32]], shape=(3, 4), dtype=int32)

# passing named lists.
# WARNING: if passing a named list, the order of elements of `.x` supplied
# to `f` is not stable. Only retrieve elements by name.
input <- list(name1 = x, name2 = x)
output <- op_vectorized_map(input, function(.x) {
  str(.x)
  list(outname1 = .x$name1 + 10,
       outname2 = .x$name2 + 20)
})
```

```
## List of 2
##  $ name1:<tf.Tensor 'loop_body/GatherV2:0' shape=(4) dtype=int32>
##  $ name2:<tf.Tensor 'loop_body/GatherV2_1:0' shape=(4) dtype=int32>

output

## $outname1
## tf.Tensor(
## [[11 12 13 14]
##  [15 16 17 18]
##  [19 20 21 22]], shape=(3, 4), dtype=int32)
##
## $outname2
## tf.Tensor(
## [[21 22 23 24]
##  [25 26 27 28]
##  [29 30 31 32]], shape=(3, 4), dtype=int32)

# passing a tuple() is equivalent to passing an unnamed list()
input <- tuple(x, x)
output <- op_vectorized_map(input, function(.x) {
  str(.x)
  list(.x[[1]] + 10)
})

## List of 2
##  $ :<tf.Tensor 'loop_body/GatherV2:0' shape=(4) dtype=int32>
##  $ :<tf.Tensor 'loop_body/GatherV2_1:0' shape=(4) dtype=int32>

output

## [[1]]
## tf.Tensor(
## [[11 12 13 14]
##  [15 16 17 18]
##  [19 20 21 22]], shape=(3, 4), dtype=int32)
```

Debugging `f`

Even in eager contexts, `op_vectorized_map()` may trace `f`. In that case, if you want to eagerly debug `f` (e.g., with `browser()`), you can swap in a manual (slow) implementation of `op_vectorized_map()`. Note this example debug implementation does not handle all the same edge cases as `op_vectorized_map()`, in particular, if `f` returns a structure of multiple tensors.

```
op_vectorized_map_debug <- function(elements, fn) {

  if (!is.list(elements)) {
    # `elements` is a single tensor
    batch_size <- op_shape(elements)[[1]]
    out <- elements |>
      op_split(batch_size) |>
      lapply(fn) |>
      op_stack()
    return(out)
  }

  # `elements` is a list of tensors
  batch_size <- elements[[1]] |> op_shape() |> _[[1]]
  elements |>
    lapply(\(e) op_split(e, batch_size)) |>
    zip_lists() |>
    lapply(fn) |>
    op_stack()

}
```

`op_vstack` *Stack tensors in sequence vertically (row wise).*

Description

Stack tensors in sequence vertically (row wise).

Usage

```
op_vstack(xs, ...)
```

Arguments

`xs, ...`	Sequence of tensors.

Value

Tensor formed by stacking the given tensors.

op_where *Return elements chosen from* x1 *or* x2 *depending on* condition.

Description

Return elements chosen from x1 or x2 depending on condition.

Usage

```
op_where(condition, x1 = NULL, x2 = NULL)
```

Arguments

condition	Where TRUE, yield x1, otherwise yield x2.
x1	Values from which to choose when condition is TRUE.
x2	Values from which to choose when condition is FALSE.

Value

A tensor with elements from x1 where condition is TRUE, and elements from x2 where condition is FALSE.

`op_while_loop` *While loop implementation.*

Description

While loop implementation.

Usage

```
op_while_loop(cond, body, loop_vars, maximum_iterations = NULL)
```

Arguments

`cond`	A callable that represents the termination condition of the loop. Must accept a `loop_vars` like structure as an argument. If `loop_vars` is a tuple or unnamed list, each element of `loop_vars` will be passed positionally to the callable.
`body`	A callable that represents the loop body. Must accept a `loop_vars` like structure as an argument, and return update value with the same structure. If `loop_vars` is a tuple or unnamed list, each element of `loop_vars` will be passed positionally to the callable.
`loop_vars`	An arbitrary nested structure of tensor state to persist across loop iterations.
`maximum_iterations`	Optional maximum number of iterations of the while loop to run. If provided, the `cond` output is AND-ed with an additional condition ensuring the number of iterations executed is no greater than `maximum_iterations`.

Value

A list of tensors, has the same shape and dtype as `loop_vars`.

Examples

```
i <- 0
loop_vars <- list(i)

# cond() must return a scalar bool
cond <- function(i) i < 10L

# body must return same shape as loop_vars
body <- function(i) list(i + 1L)

op_while_loop(cond, body, loop_vars)

## [[1]]
## tf.Tensor(10.0, shape=(), dtype=float32)

x <- 0; y <- 1
cond <- \(x, y) x < 10
body <- \(x, y) list(x+1, y+1)
op_while_loop(cond, body, list(x, y))

## [[1]]
## tf.Tensor(10.0, shape=(), dtype=float32)
##
## [[2]]
## tf.Tensor(11.0, shape=(), dtype=float32)
```

op_zeros *Return a new tensor of given shape and type, filled with zeros.*

Description

Return a new tensor of given shape and type, filled with zeros.

Usage

```
op_zeros(shape, dtype = NULL)
```

Arguments

shape	Shape of the new tensor.
dtype	Desired data type of the tensor.

Value

Tensor of zeros with the given shape and dtype.

op_zeros_like *Return a tensor of zeros with the same shape and type as* x.

Description

Return a tensor of zeros with the same shape and type as x.

Usage

```
op_zeros_like(x, dtype = NULL)
```

Arguments

x	Input tensor.
dtype	Overrides the data type of the result.

Value

A tensor of zeros with the same shape and type as x.

pad_sequences *Pads sequences to the same length.*

Description

This function transforms a list (of length num_samples) of sequences (lists of integers) into a 2D NumPy array of shape (num_samples, num_timesteps). num_timesteps is either the maxlen argument if provided, or the length of the longest sequence in the list.

Sequences that are shorter than num_timesteps are padded with value until they are num_timesteps long.

Sequences longer than num_timesteps are truncated so that they fit the desired length.

The position where padding or truncation happens is determined by the arguments padding and truncating, respectively. Pre-padding or removing values from the beginning of the sequence is the default.

```
sequence <- list(c(1), c(2, 3), c(4, 5, 6))
pad_sequences(sequence)
```

```
##      [,1] [,2] [,3]
## [1,]    0    0    1
```

```
## [2,]    0    2    3
## [3,]    4    5    6

pad_sequences(sequence, value=-1)

##      [,1] [,2] [,3]
## [1,]   -1   -1    1
## [2,]   -1    2    3
## [3,]    4    5    6

pad_sequences(sequence, padding='post')

##      [,1] [,2] [,3]
## [1,]    1    0    0
## [2,]    2    3    0
## [3,]    4    5    6

pad_sequences(sequence, maxlen=2)

##      [,1] [,2]
## [1,]    0    1
## [2,]    2    3
## [3,]    5    6
```

Usage

```
pad_sequences(
  sequences,
  maxlen = NULL,
  dtype = "int32",
  padding = "pre",
  truncating = "pre",
  value = 0
)
```

Arguments

sequences	List of sequences (each sequence is a list of integers).
maxlen	Optional Int, maximum length of all sequences. If not provided, sequences will be padded to the length of the longest individual sequence.
dtype	(Optional, defaults to "int32"). Type of the output sequences. To pad sequences with variable length strings, you can use object.
padding	String, "pre" or "post" (optional, defaults to "pre"): pad either before or after each sequence.

truncating	String, "pre" or "post" (optional, defaults to "pre"): remove values from sequences larger than maxlen, either at the beginning or at the end of the sequences.
value	Float or String, padding value. (Optional, defaults to 0)

Value

Array with shape (len(sequences), maxlen)

plot.keras.src.models.model.Model

Plot a Keras model

Description

Plot a Keras model

Usage

```
## S3 method for class 'keras.src.models.model.Model'
plot(
  x,
  show_shapes = FALSE,
  show_dtype = FALSE,
  show_layer_names = FALSE,
  ...,
  rankdir = "TB",
  expand_nested = FALSE,
  dpi = 200,
  layer_range = NULL,
  show_layer_activations = FALSE,
  show_trainable = NA,
  to_file = NULL
)
```

Arguments

x	A Keras model instance
show_shapes	whether to display shape information.
show_dtype	whether to display layer dtypes.
show_layer_names	whether to display layer names.
...	passed on to Python `keras.utils.model_to_dot()`. Used for forward and backward compatibility.
rankdir	a string specifying the format of the plot: `'TB'` creates a vertical plot; `'LR'` creates a horizontal plot. (argument passed to PyDot)
expand_nested	Whether to expand nested models into clusters.
dpi	Dots per inch. Increase this value if the image text appears excessively pixelated.
layer_range	`list` containing two character strings, which is the starting layer name and ending layer name (both inclusive) indicating the range of layers for which the plot will be generated. It also accepts regex patterns instead of exact name. In such case, start predicate will be the first element it matches to `layer_range[1]` and the end predicate will be the last element it matches to `layer_range[2]`. By default `NULL` which considers all layers of model. Note that you must pass range such that the resultant subgraph must be complete.
show_layer_activations	Display layer activations (only for layers that have an `activation` property).
show_trainable	whether to display if a layer is trainable.
to_file	File name of the plot image. If `NULL` (the default), the model is drawn on the default graphics device. Otherwise, a file is saved.

Value

Nothing, called for it's side effects.

Raises

ValueError: if `plot(model)` is called before the model is built, unless a `input_shape =` argument was supplied to `keras_model_sequential()`.

Requirements

This function requires pydot and graphviz. `pydot` is by default installed by `install_keras()`, but if you installed keras by other means, you can install `pydot` directly with :

```
reticulate::py_install("pydot", pip = TRUE)
```

You can install graphviz directly from here: https://graphviz.gitlab.io/download/

On most Linux platforms, can install graphviz via the package manager. For example, on Ubuntu/Debian you can install with

```
sudo apt install graphviz
```

In a conda environment, you can install graphviz with:

```
reticulate::conda_install(packages = "graphviz")
# Restart the R session after install.
```

---

plot.keras_training_history

Plot training history

Description

Plots metrics recorded during training.

Usage

```
## S3 method for class 'keras_training_history'
plot(
  x,
  y,
  metrics = NULL,
  method = c("auto", "ggplot2", "base"),
  smooth = getOption("keras.plot.history.smooth", TRUE),
  theme_bw = getOption("keras.plot.history.theme_bw", FALSE),
  ...
)
```

Arguments

x	Training history object returned from fit.keras.src.models.model.Model().
y	Unused.
metrics	One or more metrics to plot (e.g. c('loss', 'accuracy')). Defaults to plotting all captured metrics.
method	Method to use for plotting. The default "auto" will use **ggplot2** if available, and otherwise will use base graphics.
smooth	Whether a loess smooth should be added to the plot, only available for the ggplot2 method. If the number of epochs is smaller than ten, it is forced to false.
theme_bw	Use ggplot2::theme_bw() to plot the history in black and white.
...	Additional parameters to pass to the plot() method.

Value

if method == "ggplot2", the ggplot object is returned. If method == "base", then this function will draw to the graphics device and return NULL, invisibly.

---

pop_layer *Remove the last layer in a Sequential model*

Description

Remove the last layer in a Sequential model

Usage

```
pop_layer(object, rebuild = TRUE)
```

Arguments

object	Sequential keras model object
rebuild	bool. Whether to rebuild the model after removing the layer. Defaults to TRUE.

Value

The removed layer.

See Also

Other model functions:
get_config()
get_layer()
get_state_tree()
keras_model()
keras_model_sequential()
set_state_tree()
summary.keras.src.models.model.Model()

`predict.keras.src.models.model.Model`
Generates output predictions for the input samples.

Description

Generates output predictions for the input samples.

Usage

```
## S3 method for class 'keras.src.models.model.Model'
predict(
  object,
  x,
  ...,
  batch_size = NULL,
  verbose = getOption("keras.verbose", default = "auto"),
  steps = NULL,
  callbacks = NULL
)
```

Arguments

`object`	Keras model object
`x`	Input samples. It can be: • A array (or array-like), or a list of arrays (in case the model has multiple inputs). • A backend-native tensor, or a list of tensors (in case the model has multiple inputs). • A TF Dataset. • A Python generator function.
`...`	For forward/backward compatability.
`batch_size`	Integer or `NULL`. Number of samples per batch of computation. If unspecified, `batch_size` will default to `32`. Do not specify the `batch_size` if your input data `x` is in the form of a TF Dataset or a generator (since they generate batches).

verbose	"auto", 0, 1, or 2. Verbosity mode. 0 = silent, 1 = progress bar, 2 = one line per epoch. "auto" becomes 1 for most cases, 2 if in a knitr render or running on a distributed training server. Note that the progress bar is not particularly useful when logged to a file, so verbose=2 is recommended when not running interactively (e.g., in a production environment). Defaults to "auto".
steps	Total number of steps (batches of samples) to draw before declaring the prediction round finished. If steps is NULL, predict() will run until x is exhausted. In the case of an infinitely repeating dataset, predict() will run indefinitely.
callbacks	List of Callback instances. List of callbacks to apply during prediction.

Details

Computation is done in batches. This method is designed for batch processing of large numbers of inputs. It is not intended for use inside of loops that iterate over your data and process small numbers of inputs at a time.

For small numbers of inputs that fit in one batch, directly call the model model$call for faster execution, e.g., model(x), or model(x, training = FALSE) if you have layers such as BatchNormalization that behave differently during inference.

Value

R array(s) of predictions.

Note

See this FAQ entry for more details about the difference between Model methods predict() and call().

train_on_batch()

---

predict_on_batch *Returns predictions for a single batch of samples.*

Description

Returns predictions for a single batch of samples.

Usage

```
predict_on_batch(object, x)
```

Arguments

object	Keras model object
x	Input data. It must be array-like.

Value

Array(s) of predictions.

train_on_batch()

---

process_utils *Preprocessing and postprocessing utilities*

Description

These functions are used to preprocess and postprocess inputs and outputs of Keras applications.

Usage

```
application_preprocess_inputs(model, x, ..., data_format = NULL)

application_decode_predictions(model, preds, top = 5L, ...)
```

Arguments

model	A Keras model initialized using any application_ function.
x	A batch of inputs to the model. If x is missing, then the preprocess_input function appropriate for model is returned.
...	Additional arguments passed to the preprocessing or decoding function.
data_format	Optional data format of the image tensor/array. NULL means the global setting config_image_data_format() is used (unless you changed it, it uses "channels_last"). Defaults to NULL.
preds	A batch of outputs from the model.
top	The number of top predictions to return.

Value

- A list of decoded predictions in case of `application_decode_predictions()`.
- A batch of preprocessed inputs in case of `application_preprocess_inputs()`.

Functions

- `application_preprocess_inputs()`: Pre-process inputs to be used in the model
- `application_decode_predictions()`: Decode predictions from the model

Examples

```
## Not run:
model <- application_convnext_tiny()

inputs <- random_normal(c(32, 224, 224, 3))
processed_inputs <- application_preprocess_inputs(model, inputs)

preds <- random_normal(c(32, 1000))
decoded_preds <- application_decode_predictions(model, preds)

## End(Not run)
```

---

quantize_weights *Quantize the weights of a model.*

Description

Note that the model must be built first before calling this method. `quantize_weights()` will recursively call `layer$quantize(mode)` in all layers and will be skipped if the layer doesn't implement the function.

Currently only `Dense` and `EinsumDense` layers support quantization.

Usage

```
quantize_weights(object, mode, ...)
```

Arguments

`object`	A Keras Model or Layer.
`mode`	The mode of the quantization. Only 'int8' is supported at this time.
`...`	Passed on to the `object` quantization method.

Value

`model`, invisibly. Note this is just a convenience for usage with `|>`, the model is modified in-place.

See Also

Other layer methods:
count_params()
get_config()
get_weights()
reset_state()

---

random_beta *Draw samples from a Beta distribution.*

Description

The values are drawn from a Beta distribution parametrized by alpha and beta.

Usage

```
random_beta(shape, alpha, beta, dtype = NULL, seed = NULL)
```

Arguments

shape	The shape of the random values to generate.
alpha	Float or an array of floats representing the first parameter alpha. Must be broadcastable with beta and shape.
beta	Float or an array of floats representing the second parameter beta. Must be broadcastable with alpha and shape.
dtype	Optional dtype of the tensor. Only floating point types are supported. If not specified, config_floatx() is used, which defaults to "float32" unless you configured it otherwise (via config_set_floatx(float_dtype)).
seed	Optional R integer or instance of random_seed_generator(). By default, the seed argument is NULL, and an internal global random_seed_generator() is used. The seed argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the seed value will produce the same random values for each call. To generate different random values for repeated calls, an instance of random_seed_generator() must be provided as the seed value. Remark concerning the JAX backend: When tracing functions with the JAX backend the global random_seed_generator() is not supported. Therefore, during tracing the default value seed=NULL will produce an error, and a seed argument must be provided.

Value

A tensor of random values.

`random_binomial` *Draw samples from a Binomial distribution.*

Description

The values are drawn from a Binomial distribution with specified trial count and probability of success.

Usage

```
random_binomial(shape, counts, probabilities, dtype = NULL, seed = NULL)
```

Arguments

shape	The shape of the random values to generate.
counts	A number or array of numbers representing the number of trials. It must be broadcastable with probabilities.
probabilities	A float or array of floats representing the probability of success of an individual event. It must be broadcastable with counts.
dtype	Optional dtype of the tensor. Only floating point types are supported. If not specified, config_floatx() is used, which defaults to "float32" unless you configured it otherwise (via config_set_floatx(float_dtype)).
seed	Optional R integer or instance of random_seed_generator(). By default, the seed argument is NULL, and an internal global random_seed_generator() is used. The seed argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the seed value will produce the same random values for each call. To generate different random values for repeated calls, an instance of random_seed_generator() must be provided as the seed value. Remark concerning the JAX backend: When tracing functions with the JAX backend the global random_seed_generator() is not supported. Therefore, during tracing the default value seed=NULL will produce an error, and a seed argument must be provided.

Value

A tensor of random values.

random_categorical *Draws samples from a categorical distribution.*

Description

This function takes as input `logits`, a 2-D input tensor with shape (batch_size, num_classes). Each row of the input represents a categorical distribution, with each column index containing the log-probability for a given class.

The function will output a 2-D tensor with shape (batch_size, num_samples), where each row contains samples from the corresponding row in `logits`. Each column index contains an independent samples drawn from the input distribution.

```
x <- matrix(c(100, .1, 99), nrow = 1)
random_categorical(x, num_samples = 5, seed = 1234)
```

```
## tf.Tensor([[3 1 1 3 3]], shape=(1, 5), dtype=int32)
```

```
random_categorical(x, num_samples = 5, seed = 1234,
                   zero_indexed = TRUE)
```

```
## tf.Tensor([[2 0 0 2 2]], shape=(1, 5), dtype=int32)
```

```
op_take(x, random_categorical(x, num_samples = 5, seed = 1234))
```

```
## tf.Tensor([[ 99. 100. 100.  99.  99.]], shape=(1, 5), dtype=float64)

op_take(x, random_categorical(x, num_samples = 5, seed = 1234,
                              zero_indexed = TRUE),
        zero_indexed = TRUE)

## tf.Tensor([[ 99. 100. 100.  99.  99.]], shape=(1, 5), dtype=float64)
```

Usage

```
random_categorical(
  logits,
  num_samples,
  dtype = "int32",
  seed = NULL,
  zero_indexed = FALSE
)
```

Arguments

logits	2-D Tensor with shape (batch_size, num_classes). Each row should define a categorical distribution with the unnormalized log-probabilities for all classes.
num_samples	Int, the number of independent samples to draw for each row of the input. This will be the second dimension of the output tensor's shape.
dtype	Optional dtype of the output tensor.
seed	Optional R integer or instance of random_seed_generator(). By default, the seed argument is NULL, and an internal global random_seed_generator() is used. The seed argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the seed value will produce the same random values for each call. To generate different random values for repeated calls, an instance of random_seed_generator() must be provided as the seed value. Remark concerning the JAX backend: When tracing functions with the JAX backend the global random_seed_generator() is not supported. Therefore, during tracing the default value seed=NULL will produce an error, and a seed argument must be provided.
zero_indexed	If TRUE, the returned indices are zero-based (0 encodes to first position); if FALSE (default), the returned indices are one-based (1 encodes to first position).

Value

A 2-D tensor with (batch_size, num_samples).

random_dropout *Randomly set some values in a tensor to 0.*

Description

Randomly set some portion of values in the tensor to 0.

Usage

```
random_dropout(inputs, rate, noise_shape = NULL, seed = NULL)
```

Arguments

inputs	A tensor
rate	numeric
noise_shape	A shape() value
seed	Initial seed for the random number generator

Value

A tensor that is a copy of inputs with some values set to 0.

random_gamma *Draw random samples from the Gamma distribution.*

Description

Draw random samples from the Gamma distribution.

Usage

```
random_gamma(shape, alpha, dtype = NULL, seed = NULL)
```

Arguments

shape	The shape of the random values to generate.
alpha	Float, the parameter of the distribution.
dtype	Optional dtype of the tensor. Only floating point types are supported. If not specified, config_floatx() is used, which defaults to float32 unless you configured it otherwise (via config_set_floatx(float_dtype)).
seed	Optional R integer or instance of random_seed_generator(). By default, the seed argument is NULL, and an internal global random_seed_generator() is used. The seed argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the seed value will produce the same random values for each call. To generate different random values for repeated calls, an instance of random_seed_generator() must be provided as the seed value. Remark concerning the JAX backend: When tracing functions with the JAX backend the global random_seed_generator() is not supported. Therefore, during tracing the default value seed=NULL will produce an error, and a seed argument must be provided.

Value

`random_integer` *Draw random integers from a uniform distribution.*

Description

The generated values follow a uniform distribution in the range `[minval, maxval)`. The lower bound `minval` is included in the range, while the upper bound `maxval` is excluded.

`dtype` must be an integer type.

Usage

```
random_integer(shape, minval, maxval, dtype = "int32", seed = NULL)
```

Arguments

`shape`	The shape of the random values to generate.
`minval`	integer, lower bound of the range of random values to generate (inclusive).
`maxval`	integer, upper bound of the range of random values to generate (exclusive).
`dtype`	Optional dtype of the tensor. Only integer types are supported. If not specified, `"int32"` is used.
`seed`	Optional R integer or instance of `random_seed_generator()`. By default, the `seed` argument is `NULL`, and an internal global `random_seed_generator()` is used. The `seed` argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the `seed` value will produce the same random values for each call. To generate different random values for repeated calls, an instance of `random_seed_generator()` must be provided as the `seed` value. Remark concerning the JAX backend: When tracing functions with the JAX backend the global `random_seed_generator()` is not supported. Therefore, during tracing the default value `seed=NULL` will produce an error, and a `seed` argument must be provided.

Value

A tensor of random values.

`random_normal` *Draw random samples from a normal (Gaussian) distribution.*

Description

Draw random samples from a normal (Gaussian) distribution.

Usage

```
random_normal(shape, mean = 0, stddev = 1, dtype = NULL, seed = NULL)
```

Arguments

shape	The shape of the random values to generate.
mean	Float, defaults to 0. Mean of the random values to generate.
stddev	Float, defaults to 1. Standard deviation of the random values to generate.
dtype	Optional dtype of the tensor. Only floating point types are supported. If not specified, config_floatx() is used, which defaults to float32 unless you configured it otherwise (via config_set_floatx(float_dtype)).
seed	Optional R integer or instance of random_seed_generator(). By default, the seed argument is NULL, and an internal global random_seed_generator() is used. The seed argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the seed value will produce the same random values for each call. To generate different random values for repeated calls, an instance of random_seed_generator() must be provided as the seed value. Remark concerning the JAX backend: When tracing functions with the JAX backend the global random_seed_generator() is not supported. Therefore, during tracing the default value seed=NULL will produce an error, and a seed argument must be provided.

Value

A tensor of random values.

`random_seed_generator` *Generates variable seeds upon each call to a function generating random numbers.*

Description

In Keras, all random number generators (such as `random_normal()`) are stateless, meaning that if you pass an integer seed to them (such as `seed=42`), they will return the same values for repeated calls. To get different values for each call, a `SeedGenerator` providing the state of the random generator has to be used.

Note that all the random number generators have a default seed of `NULL`, which implies that an internal global `SeedGenerator` is used. If you need to decouple the RNG from the global state you can provide a local `StateGenerator` with either a deterministic or random initial state.

Remark concerning the JAX backen: Note that the use of a local `StateGenerator` as seed argument is required for JIT compilation of RNG with the JAX backend, because the use of global state is not supported.

Usage

```
random_seed_generator(seed = NULL, name = NULL, ...)
```

Arguments

`seed`	Initial seed for the random number generator
`name`	String, name for the object
`...`	For forward/backward compatability.

Value

A SeedGenerator instance, which can be passed as the seed = argument to other random tensor generators.

Examples

```
seed_gen <- random_seed_generator(seed = 42)
values <- random_normal(shape = c(2, 3), seed = seed_gen)
new_values <- random_normal(shape = c(2, 3), seed = seed_gen)
```

Usage in a layer:

```
layer_dropout2 <- new_layer_class(
  "dropout2",
  initialize = function(...) {
    super$initialize(...)
    self$seed_generator <- random_seed_generator(seed = 1337)
  },
  call = function(x, training = FALSE) {
    if (training) {
      return(random_dropout(x, rate = 0.5, seed = self$seed_generator))
    }
    return(x)
  }
)

out <- layer_dropout(rate = 0.8)
out(op_ones(10), training = TRUE)

## tf.Tensor([0. 5. 5. 0. 0. 0. 0. 0. 0. 0.], shape=(10), dtype=float32)
```

random_shuffle *Shuffle the elements of a tensor uniformly at random along an axis.*

Description

Shuffle the elements of a tensor uniformly at random along an axis.

Usage

```
random_shuffle(x, axis = 1L, seed = NULL)
```

Arguments

x	The tensor to be shuffled.
axis	An integer specifying the axis along which to shuffle. Defaults to 0.
seed	Optional R integer or instance of random_seed_generator(). By default, the seed argument is NULL, and an internal global random_seed_generator() is used. The seed argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the seed value will produce the same random values for each call. To generate different random values for repeated calls, an instance of random_seed_generator() must be provided as the seed value. Remark concerning the JAX backend: When tracing functions with the JAX backend the global random_seed_generator() is not supported. Therefore, during tracing the default value seed=NULL will produce an error, and a seed argument must be provided.

Value

A tensor, a copy of x with the axis axis shuffled.

`random_truncated_normal` *Draw samples from a truncated normal distribution.*

Description

The values are drawn from a normal distribution with specified mean and standard deviation, discarding and re-drawing any samples that are more than two standard deviations from the mean.

Usage

```
random_truncated_normal(shape, mean = 0, stddev = 1, dtype = NULL, seed = NULL)
```

Arguments

shape	The shape of the random values to generate.
mean	Float, defaults to 0. Mean of the random values to generate.
stddev	Float, defaults to 1. Standard deviation of the random values to generate.
dtype	Optional dtype of the tensor. Only floating point types are supported. If not specified, `config_floatx()` is used, which defaults to `float32` unless you configured it otherwise (via `config_set_floatx(float_dtype)`)
seed	Optional R integer or instance of `random_seed_generator()`. By default, the `seed` argument is `NULL`, and an internal global `random_seed_generator()` is used. The `seed` argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the `seed` value will produce the same random values for each call. To generate different random values for repeated calls, an instance of `random_seed_generator()` must be provided as the `seed` value. Remark concerning the JAX backend: When tracing functions with the JAX backend the global `random_seed_generator()` is not supported. Therefore, during tracing the default value `seed=NULL` will produce an error, and a `seed` argument must be provided.

random_uniform *Draw samples from a uniform distribution.*

Description

The generated values follow a uniform distribution in the range `[minval, maxval)`. The lower bound `minval` is included in the range, while the upper bound `maxval` is excluded.

`dtype` must be a floating point type, the default range is `[0, 1)`.

Usage

```
random_uniform(shape, minval = 0, maxval = 1, dtype = NULL, seed = NULL)
```

Arguments

shape	The shape of the random values to generate.
minval	Float, defaults to 0. Lower bound of the range of random values to generate (inclusive).
maxval	Float, defaults to 1. Upper bound of the range of random values to generate (exclusive).
dtype	Optional dtype of the tensor. Only floating point types are supported. If not specified, `config_floatx()` is used, which defaults to `float32` unless you configured it otherwise (via `config_set_floatx(float_dtype)`)
seed	Optional R integer or instance of `random_seed_generator()`. By default, the `seed` argument is `NULL`, and an internal global `random_seed_generator()` is used. The `seed` argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the `seed` value will produce the same random values for each call. To generate different random values for repeated calls, an instance of `random_seed_generator()` must be provided as the `seed` value. Remark concerning the JAX backend: When tracing functions with the JAX backend the global `random_seed_generator()` is not supported. register_keras_serializable

Registers a custom object with the Keras serialization framework.

Description

This function registers a custom class or function with the Keras custom object registry, so that it can be serialized and deserialized without needing an entry in the user-provided custom_objects argument. It also injects a function that Keras will call to get the object's serializable string key.

Note that to be serialized and deserialized, classes must implement the get_config() method. Functions do not have this requirement.

The object will be registered under the key 'package>name' where name, defaults to the object name if not passed.

Usage

```
register_keras_serializable(object, name = NULL, package = NULL)
```

Arguments

object	A keras object.
name	The name to serialize this class under in this package.
package	The package that this class belongs to. This is used for the key (which is "package>name") to identify the class. Defaults to the current package name, or "Custom" outside of a package.

Value

object is returned invisibly, for convenient piping. This is primarily called for side effects.

Examples

```
# Note that `'my_package'` is used as the `package` argument here, and since
# the `name` argument is not provided, `'MyDense'` is used as the `name`.
layer_my_dense <- Layer("MyDense")
register_keras_serializable(layer_my_dense, package = "my_package")

MyDense <- environment(layer_my_dense)$`__class__` # the python class obj
stopifnot(exprs = {
  get_registered_object('my_package>MyDense') == MyDense
  get_registered_name(MyDense) == 'my_package>MyDense'
})
```

regularizer_l1 *A regularizer that applies a L1 regularization penalty.*

Description

The L1 regularization penalty is computed as: `loss = l1 * reduce_sum(abs(x))`

L1 may be passed to a layer as a string identifier:

```
dense <- layer_dense(units = 3, kernel_regularizer = 'l1')
```

In this case, the default value used is `l1=0.01`.

Usage

```
regularizer_l1(l1 = 0.01)
```

Arguments

l1	float, L1 regularization factor.

Value

A Regularizer instance that can be passed to layer constructors or used as a standalone object.

See Also

- https://keras.io/api/layers/regularizers#l1-class

Other regularizers:
regularizer_l1_l2()
regularizer_l2()
regularizer_orthogonal()

---

regularizer_l1_l2 *A regularizer that applies both L1 and L2 regularization penalties.*

Description

The L1 regularization penalty is computed as: loss = l1 * reduce_sum(abs(x))

The L2 regularization penalty is computed as loss = l2 * reduce_sum(square(x))

L1L2 may be passed to a layer as a string identifier:

```
dense <- layer_dense(units = 3, kernel_regularizer = 'L1L2')
```

In this case, the default values used are l1=0.01 and l2=0.01.

Usage

```
regularizer_l1_l2(l1 = 0, l2 = 0)
```

Arguments

l1	float, L1 regularization factor.
l2	float, L2 regularization factor.

Value

A Regularizer instance that can be passed to layer constructors or used as a standalone object.

See Also

- https://keras.io/api/layers/regularizers#l1l2-class

Other regularizers:
regularizer_l1()
regularizer_l2()
regularizer_orthogonal()

---

regularizer_l2 *A regularizer that applies a L2 regularization penalty.*

Description

The L2 regularization penalty is computed as: `loss = l2 * reduce_sum(square(x))`

L2 may be passed to a layer as a string identifier:

```
dense <- layer_dense(units = 3, kernel_regularizer='l2')
```

In this case, the default value used is `l2=0.01`.

Usage

```
regularizer_l2(l2 = 0.01)
```

Arguments

l2	float, L2 regularization factor.

Value

A `Regularizer` instance that can be passed to layer constructors or used as a standalone object.

See Also

- https://keras.io/api/layers/regularizers#l2-class

Other regularizers:
regularizer_l1()
regularizer_l1_l2()
regularizer_orthogonal()

regularizer_orthogonal *Regularizer that encourages input vectors to be orthogonal to each other.*

Description

It can be applied to either the rows of a matrix (`mode="rows"`) or its columns (`mode="columns"`). When applied to a `Dense` kernel of shape `(input_dim, units)`, rows mode will seek to make the feature vectors (i.e. the basis of the output space) orthogonal to each other.

Usage

```
regularizer_orthogonal(factor = 0.01, mode = "rows")
```

Arguments

`factor`	Float. The regularization factor. The regularization penalty will be proportional to `factor` times the mean of the dot products between the L2-normalized rows (if `mode="rows"`, or columns if `mode="columns"`) of the inputs, excluding the product of each row/column with itself. Defaults to `0.01`.
`mode`	String, one of `{"rows", "columns"}`. Defaults to `"rows"`. In rows mode, the regularization effect seeks to make the rows of the input orthogonal to each other. In columns mode, it seeks to make the columns of the input orthogonal to each other.

Value

A `Regularizer` instance that can be passed to layer constructors or used as a standalone object.

Examples

```
regularizer <- regularizer_orthogonal(factor=0.01)
layer <- layer_dense(units=4, kernel_regularizer=regularizer)
```

See Also

- https://keras.io/api/layers/regularizers#orthogonalregularizer-class

Other regularizers:
regularizer_l1()
regularizer_l1_l2()
regularizer_l2()

reset_state *Reset the state for a model, layer or metric.*

Description

Reset the state for a model, layer or metric.

Usage

```
reset_state(object)
```

Arguments

object	Model, Layer, or Metric instance Not all Layers have resettable state (E.g., adapt()-able preprocessing layers and rnn layers have resettable state, but a layer_dense() does not). Calling this on a Layer instance without any resettable-state will error.

Value

object, invisibly.

See Also

Other layer methods:
count_params()
get_config()
get_weights()
quantize_weights()

rnn_cells_stack *Wrapper allowing a stack of RNN cells to behave as a single cell.*

Description

Used to implement efficient stacked RNNs.

Usage

```
rnn_cells_stack(cells, ...)
```

Arguments

cells	List of RNN cell instances.
...	Unnamed arguments are treated as additional cells. Named arguments are passed on to the underlying layer.

Value

A Layer instance, which is intended to be used with layer_rnn().

Example

```
batch_size <- 3
sentence_length <- 5
num_features <- 2
new_shape <- c(batch_size, sentence_length, num_features)
x <- array(1:30, dim = new_shape)

rnn_cells <- lapply(1:2, function(x) rnn_cell_lstm(units = 128))
stacked_lstm <- rnn_cells_stack(rnn_cells)
lstm_layer <- layer_rnn(cell = stacked_lstm)

result <- lstm_layer(x)
str(result)

## <tf.Tensor: shape=(3, 128), dtype=float32, numpy=. . . >
```

rnn_cell_gru *Cell class for the GRU layer.*

Description

This class processes one step within the whole time sequence input, whereas layer_gru() processes the whole sequence.

Usage

```
rnn_cell_gru(
  units,
  activation = "tanh",
  recurrent_activation = "sigmoid",
  use_bias = TRUE,
  kernel_initializer = "glorot_uniform",
  recurrent_initializer = "orthogonal",
  bias_initializer = "zeros",
  kernel_regularizer = NULL,
  recurrent_regularizer = NULL,
```

```
  bias_regularizer = NULL,
  kernel_constraint = NULL,
  recurrent_constraint = NULL,
  bias_constraint = NULL,
  dropout = 0,
  recurrent_dropout = 0,
  reset_after = TRUE,
  seed = NULL,
  ...
)
```

Arguments

units	Positive integer, dimensionality of the output space.
activation	Activation function to use. Default: hyperbolic tangent (tanh). If you pass NULL, no activation is applied (ie. "linear" activation: a(x) = x).
recurrent_activation	Activation function to use for the recurrent step. Default: sigmoid (sigmoid). If you pass NULL, no activation is applied (ie. "linear" activation: a(x) = x).
use_bias	Boolean, (default TRUE), whether the layer should use a bias vector.
kernel_initializer	Initializer for the kernel weights matrix, used for the linear transformation of the inputs. Default: "glorot_uniform".
recurrent_initializer	Initializer for the recurrent_kernel weights matrix, used for the linear transformation of the recurrent state. Default: "orthogonal".
bias_initializer	Initializer for the bias vector. Default: "zeros".
kernel_regularizer	Regularizer function applied to the kernel weights matrix. Default: NULL.
recurrent_regularizer	Regularizer function applied to the recurrent_kernel weights matrix. Default: NULL.
bias_regularizer	Regularizer function applied to the bias vector. Default: NULL.
kernel_constraint	Constraint function applied to the kernel weights matrix. Default: NULL.
recurrent_constraint	Constraint function applied to the recurrent_kernel weights matrix. Default: NULL.
bias_constraint	Constraint function applied to the bias vector. Default: NULL.
dropout	Float between 0 and 1. Fraction of the units to drop for the linear transformation of the inputs. Default: 0.
recurrent_dropout	Float between 0 and 1. Fraction of the units to drop for the linear transformation of the recurrent state. Default: 0.

reset_after	GRU convention (whether to apply reset gate after or before matrix multiplication). FALSE = "before", TRUE = "after" (default and cuDNN compatible).
seed	Random seed for dropout.
...	For forward/backward compatability.

Value

A Layer instance, which is intended to be used with layer_rnn().

Call Arguments

- inputs: A 2D tensor, with shape (batch, features).
- states: A 2D tensor with shape (batch, units), which is the state from the previous time step.
- training: Python boolean indicating whether the layer should behave in training mode or in inference mode. Only relevant when dropout or recurrent_dropout is used.

Examples

```
inputs <- random_uniform(c(32, 10, 8))
outputs <- inputs |> layer_rnn(rnn_cell_gru(4))
shape(outputs)

## shape(32, 4)

rnn <- layer_rnn(
   cell = rnn_cell_gru(4),
   return_sequences=TRUE,
   return_state=TRUE)
c(whole_sequence_output, final_state) %<-% rnn(inputs)
shape(whole_sequence_output)

## shape(32, 10, 4)

shape(final_state)

## shape(32, 4)

rnn_cell_lstm *Cell class for the LSTM layer.*

Description

This class processes one step within the whole time sequence input, whereas layer_lstm() processes the whole sequence.

Usage

```
rnn_cell_lstm(
  units,
  activation = "tanh",
  recurrent_activation = "sigmoid",
  use_bias = TRUE,
  kernel_initializer = "glorot_uniform",
  recurrent_initializer = "orthogonal",
  bias_initializer = "zeros",
  unit_forget_bias = TRUE,
  kernel_regularizer = NULL,
  recurrent_regularizer = NULL,
  bias_regularizer = NULL,
  kernel_constraint = NULL,
  recurrent_constraint = NULL,
  bias_constraint = NULL,
  dropout = 0,
  recurrent_dropout = 0,
  seed = NULL,
  ...
)
```

Arguments

units	Positive integer, dimensionality of the output space.
activation	Activation function to use. Default: hyperbolic tangent (tanh). If you pass NULL, no activation is applied (ie. "linear" activation: a(x) = x).
recurrent_activation	Activation function to use for the recurrent step. Default: sigmoid (sigmoid). If you pass NULL, no activation is applied (ie. "linear" activation: a(x) = x).

use_bias Boolean, (default TRUE), whether the layer should use a bias vector.

kernel_initializer
Initializer for the kernel weights matrix, used for the linear transformation of the inputs. Default: "glorot_uniform".

recurrent_initializer
Initializer for the recurrent_kernel weights matrix, used for the linear transformation of the recurrent state. Default: "orthogonal".

bias_initializer
Initializer for the bias vector. Default: "zeros".

unit_forget_bias
Boolean (default TRUE). If TRUE, add 1 to the bias of the forget gate at initialization. Setting it to TRUE will also force bias_initializer="zeros". This is recommended in Jozefowicz et al.

kernel_regularizer
Regularizer function applied to the kernel weights matrix. Default: NULL.

recurrent_regularizer
Regularizer function applied to the recurrent_kernel weights matrix. Default: NULL.

bias_regularizer
Regularizer function applied to the bias vector. Default: NULL.

kernel_constraint
Constraint function applied to the kernel weights matrix. Default: NULL.

recurrent_constraint
Constraint function applied to the recurrent_kernel weights matrix. Default: NULL.

bias_constraint
Constraint function applied to the bias vector. Default: NULL.

dropout Float between 0 and 1. Fraction of the units to drop for the linear transformation of the inputs. Default: 0.

recurrent_dropout
Float between 0 and 1. Fraction of the units to drop for the linear transformation of the recurrent state. Default: 0.

seed Random seed for dropout.

... For forward/backward compatability.

Value

A Layer instance, which is intended to be used with layer_rnn().

Call Arguments

- inputs: A 2D tensor, with shape (batch, features).
- states: A 2D tensor with shape (batch, units), which is the state from the previous time step.
- training: Boolean indicating whether the layer should behave in training mode or in inference mode. Only relevant when dropout or recurrent_dropout is used.

Examples

```
inputs <- random_uniform(c(32, 10, 8))
output <- inputs |>
  layer_rnn(cell = rnn_cell_lstm(4))
shape(output)

## shape(32, 4)

rnn <- layer_rnn(cell = rnn_cell_lstm(4),
                 return_sequences = T,
                 return_state = T)
c(whole_sequence_output, ...final_state) %<-% rnn(inputs)
str(whole_sequence_output)

## <tf.Tensor: shape=(32, 10, 4), dtype=float32, numpy=. . . >

str(final_state)

## List of 2
##  $ :<tf.Tensor: shape=(32, 4), dtype=float32, numpy=. . . >
##  $ :<tf.Tensor: shape=(32, 4), dtype=float32, numpy=. . . >

`rnn_cell_simple` *Cell class for SimpleRNN.*

Description

This class processes one step within the whole time sequence input, whereas `layer_simple_rnn()` processes the whole sequence.

Usage

```
rnn_cell_simple(
  units,
  activation = "tanh",
  use_bias = TRUE,
  kernel_initializer = "glorot_uniform",
  recurrent_initializer = "orthogonal",
  bias_initializer = "zeros",
  kernel_regularizer = NULL,
  recurrent_regularizer = NULL,
  bias_regularizer = NULL,
  kernel_constraint = NULL,
  recurrent_constraint = NULL,
  bias_constraint = NULL,
  dropout = 0,
  recurrent_dropout = 0,
  seed = NULL,
  ...
)
```

Arguments

units	Positive integer, dimensionality of the output space.
activation	Activation function to use. Default: hyperbolic tangent (tanh). If you pass NULL, no activation is applied (ie. "linear" activation: a(x) = x).
use_bias	Boolean, (default TRUE), whether the layer should use a bias vector.
kernel_initializer	Initializer for the kernel weights matrix, used for the linear transformation of the inputs. Default: "glorot_uniform".
recurrent_initializer	Initializer for the recurrent_kernel weights matrix, used for the linear transformation of the recurrent state. Default: "orthogonal".
bias_initializer	Initializer for the bias vector. Default: "zeros".
kernel_regularizer	Regularizer function applied to the kernel weights matrix. Default: NULL.
recurrent_regularizer	Regularizer function applied to the recurrent_kernel weights matrix. Default: NULL.
bias_regularizer	Regularizer function applied to the bias vector. Default: NULL.
kernel_constraint	Constraint function applied to the kernel weights matrix. Default: NULL.
recurrent_constraint	Constraint function applied to the recurrent_kernel weights matrix. Default: NULL.

bias_constraint
: Constraint function applied to the bias vector. Default: NULL.

dropout
: Float between 0 and 1. Fraction of the units to drop for the linear transformation of the inputs. Default: 0.

recurrent_dropout
: Float between 0 and 1. Fraction of the units to drop for the linear transformation of the recurrent state. Default: 0.

seed
: Random seed for dropout.

...
: For forward/backward compatability.

Value

A Layer instance, which is intended to be used with layer_rnn().

Call Arguments

- sequence: A 2D tensor, with shape (batch, features).
- states: A 2D tensor with shape (batch, units), which is the state from the previous time step.
- training: Python boolean indicating whether the layer should behave in training mode or in inference mode. Only relevant when dropout or recurrent_dropout is used.

Examples

```
inputs <- random_uniform(c(32, 10, 8))
rnn <- layer_rnn(cell = rnn_cell_simple(units = 4))
output <- rnn(inputs)  # The output has shape `(32, 4)`.
rnn <- layer_rnn(
    cell = rnn_cell_simple(units = 4),
    return_sequences=TRUE,
    return_state=TRUE
)

save_model *Saves a model as a* .keras *file.*

Description

Saves a model as a .keras file.

Usage

```
save_model(model, filepath = NULL, overwrite = FALSE, zipped = NULL, ...)
```

Arguments

model	A keras model.
filepath	string, Path where to save the model. Must end in .keras.
overwrite	Whether we should overwrite any existing model at the target location, or instead ask the user via an interactive prompt.
zipped	Whether to save the model as a zipped .keras archive (default when saving locally), or as an unzipped directory (default when saving on the Hugging Face Hub).
...	For forward/backward compatability.

Value

If filepath is provided, then this function is called primarily for side effects, and model is returned invisibly. If filepath is not provided or NULL, then the serialized model is returned as an R raw vector.

Examples

```
model <- keras_model_sequential(input_shape = c(3)) |>
  layer_dense(5) |>
  layer_activation_softmax()

model |> save_model("model.keras")
loaded_model <- load_model("model.keras")

x <- random_uniform(c(10, 3))
stopifnot(all.equal(
  model |> predict(x),
  loaded_model |> predict(x)
))
```

The saved .keras file is a zip archive that contains:

- The model's configuration (architecture)
- The model's weights
- The model's optimizer's state (if any)

Thus models can be reinstantiated in the exact same state.

```
zip::zip_list("model.keras")[, "filename"]
```

```
## [1] "metadata.json"    "config.json"      "model.weights.h5"
```

See Also

load_model()

load_model()
load_model_weights()
register_keras_serializable()
save_model_config()
save_model_weights()
with_custom_object_scope()

`save_model_config` *Save and load model configuration as JSON*

Description

Save and re-load models configurations as JSON. Note that the representation does not include the weights, only the architecture.

Usage

```
save_model_config(model, filepath = NULL, overwrite = FALSE)

load_model_config(filepath, custom_objects = NULL)
```

Arguments

`model`	Model object to save
`filepath`	path to json file with the model config.
`overwrite`	Whether we should overwrite any existing model configuration json at `filepath`, or instead ask the user via an interactive prompt.
`custom_objects`	Optional named list mapping names to custom classes or functions to be considered during deserialization.

Details

Note: `save_model_config()` serializes the model to JSON using `serialize_keras_object()`, not `get_config()`. `serialize_keras_object()` returns a superset of `get_config()`, with additional information needed to create the class object needed to restore the model. See example for how to extract the `get_config()` value from a saved model.

Value

This is called primarily for side effects. `model` is returned, invisibly, to enable usage with the pipe.

Example

```
model <- keras_model_sequential(input_shape = 10) |> layer_dense(10)
file <- tempfile("model-config-", fileext = ".json")
save_model_config(model, file)

# load a new model instance with the same architecture but different weights
model2 <- load_model_config(file)

stopifnot(exprs = {
  all.equal(get_config(model), get_config(model2))

  # To extract the `get_config()` value from a saved model config:
  all.equal(
      get_config(model),
      structure(jsonlite::read_json(file)$config,
                "__class__" = keras_model_sequential()$`__class__`)
  )
})
```

save_model_weights *Saves all layer weights to a* .weights.h5 *file.*

Description

Saves all layer weights to a .weights.h5 file.

Usage

```
save_model_weights(model, filepath, overwrite = FALSE)
```

Arguments

model	A keras Model object
filepath	string. Path where to save the model. Must end in .weights.h5.
overwrite	Whether we should overwrite any existing model at the target location, or instead ask the user via an interactive prompt.

Value

This is called primarily for side effects. model is returned, invisibly, to enable usage with the pipe.

---

serialize_keras_object

Retrieve the full config by serializing the Keras object.

Description

serialize_keras_object() serializes a Keras object to a named list that represents the object, and is a reciprocal function of deserialize_keras_object(). See deserialize_keras_object() for more information about the full config format.

Usage

```
serialize_keras_object(obj)
```

Arguments

obj	the Keras object to serialize.

Value

A named list that represents the object config. The config is expected to contain simple types only, and can be saved as json. The object can be deserialized from the config via `deserialize_keras_object()`.

---

set_random_seed *Sets all random seeds (Python, NumPy, and backend framework, e.g. TF).*

Description

You can use this utility to make almost any Keras program fully deterministic. Some limitations apply in cases where network communications are involved (e.g. parameter server distribution), which creates additional sources of randomness, or when certain non-deterministic cuDNN ops are involved.

This sets:

- the R session seed: `set.seed()`
- the Python session seed: `import random; random.seed(seed)`
- the Python NumPy seed: `import numpy; numpy.random.seed(seed)`
- the TensorFlow seed: `tf$random$set_seed(seed)` (only if TF is installed)
- The Torch seed: `import("torch")$manual_seed(seed)` (only if the backend is torch)
- and disables Python hash randomization.

Note that the TensorFlow seed is set even if you're not using TensorFlow as your backend framework, since many workflows leverage `tf$data` pipelines (which feature random shuffling). Likewise many workflows might leverage NumPy APIs.

Usage

```
set_random_seed(seed)
```

Arguments

seed	Integer, the random seed to use.

Value

No return value, called for side effects.

set_state_tree *Assigns values to variables of the model.*

Description

This method takes a dictionary (named list) of nested variable values, which represents the state tree of the model, and assigns them to the corresponding variables of the model. The keys (list names) represent the variable names (e.g., `'trainable_variables'`, `'optimizer_variables'`), and the values are nested dictionaries containing the variable paths and their corresponding values.

Usage

```
set_state_tree(object, state_tree)
```

Arguments

`object`	A keras model.
`state_tree`	A dictionary representing the state tree of the model. The keys are the variable names, and the values are nested dictionaries representing the variable paths and their values.

---

shape *Tensor shape utility*

Description

This function can be used to get or create a tensor shape.

Usage

```
shape(...)

## S3 method for class 'keras_shape'
format(x, ..., prefix = TRUE)

## S3 method for class 'keras_shape'
print(x, ...)

## S3 method for class 'keras_shape'
```

```
x[...]

## S3 method for class 'keras_shape'
as.integer(x, ...)

## S3 method for class 'keras_shape'
Summary(..., na.rm = FALSE)

## S3 method for class 'keras_shape'
as.list(x, ...)

## S3 method for class 'keras_shape'
x == y

## S3 method for class 'keras_shape'
x != y
```

Arguments

...	A shape specification. Numerics, NULL and tensors are valid. NULL, NA, and -1L can be used to specify an unspecified dim size. Tensors are dispatched to op_shape() to extract the tensor shape. Values wrapped in I() are used asis (see examples). All other objects are coerced via as.integer().
x, y	A keras_shape object.
prefix	Whether to format the shape object with a prefix. Defaults to "shape".
na.rm	passed on to Summary group generics like prod(). Unknown axes are treated as NA.

Value

A list with a "keras_shape" class attribute. Each element of the list will be either a) NULL, b) an R integer or c) a scalar integer tensor (e.g., when supplied a TF tensor with an unspecified dimension in a function being traced).

Examples

```
shape(1, 2, 3)

## shape(1, 2, 3)
```

3 ways to specify an unknown dimension

```
shape(NA,   2, 3)
shape(NULL, 2, 3)
shape(-1,   2, 3)
```

```
## shape(NA, 2, 3)
## shape(NA, 2, 3)
## shape(NA, 2, 3)
```

Most functions that take a 'shape' argument also coerce with `shape()`

```
layer_input(c(1, 2, 3))
layer_input(shape(1, 2, 3))
```

```
## <KerasTensor shape=(None, 1, 2, 3), dtype=float32, sparse=False, ragged=False, name=keras_tensor>
## <KerasTensor shape=(None, 1, 2, 3), dtype=float32, sparse=False, ragged=False, name=keras_tensor_1>
```

You can also use `shape()` to get the shape of a tensor (excepting scalar integer tensors).

```
symbolic_tensor <- layer_input(shape(1, 2, 3))
shape(symbolic_tensor)
```

```
## shape(NA, 1, 2, 3)
```

```
eager_tensor <- op_ones(c(1,2,3))
shape(eager_tensor)
```

```
## shape(1, 2, 3)
```

```
op_shape(eager_tensor)
```

```
## shape(1, 2, 3)
```

Combine or expand shapes

```
shape(symbolic_tensor, 4)
```

```
## shape(NA, 1, 2, 3, 4)
```

```
shape(5, symbolic_tensor, 4)
```

```
## shape(5, NA, 1, 2, 3, 4)
```

Scalar integer tensors are treated as axis values. These are most commonly encountered when tracing a function in graph mode, where an axis size might be unknown.

```
tfn <- tensorflow::tf_function(function(x) {
  print(op_shape(x))
  x
},
input_signature = list(tensorflow::tf$TensorSpec(shape(1, NA, 3))))
invisible(tfn(op_ones(shape(1, 2, 3))))

## shape(1, Tensor("strided_slice:0", shape=(), dtype=int32), 3)
```

A useful pattern is to unpack the shape() with %<-%, like this:

```
c(batch_size, seq_len, channels) %<-% shape(x)

# `%<-%` also has support for skipping values
# during unpacking with `.` and `...`. For example,
# To retrieve just the first and/or last dim:
c(batch_size, ...) %<-% shape(x)
c(batch_size, ., .) %<-% shape(x)
c(..., channels) %<-% shape(x)
c(batch_size, ..., channels) %<-% shape(x)
c(batch_size, ., channels) %<-% shape(x)

echo_print <- function(x) {
  message("> ", deparse(substitute(x)));
  if(!is.null(x)) print(x)
}
tfn <- tensorflow::tf_function(function(x) {
  c(axis1, axis2, axis3) %<-% shape(x)
  echo_print(str(list(axis1 = axis1, axis2 = axis2, axis3 = axis3)))

  echo_print(shape(axis1))               # use axis1 tensor as axis value
  echo_print(shape(axis1, axis2, axis3)) # use axis1 tensor as axis value

  # use shape() to compose a new shape, e.g., in multihead attention
  n_heads <- 4
  echo_print(shape(axis1, axis2, n_heads, axis3/n_heads))

  x
},
input_signature = list(tensorflow::tf$TensorSpec(shape(NA, 4, 16))))
invisible(tfn(op_ones(shape(2, 4, 16))))

## > str(list(axis1 = axis1, axis2 = axis2, axis3 = axis3))

## List of 3
##  $ axis1:<tf.Tensor 'strided_slice:0' shape=() dtype=int32>
##  $ axis2: int 4
##  $ axis3: int 16
```

```
## > shape(axis1)

## shape(Tensor("strided_slice:0", shape=(), dtype=int32))

## > shape(axis1, axis2, axis3)

## shape(Tensor("strided_slice:0", shape=(), dtype=int32), 4, 16)

## > shape(axis1, axis2, n_heads, axis3/n_heads)

## shape(Tensor("strided_slice:0", shape=(), dtype=int32), 4, 4, 4)
```

If you want to resolve the shape of a tensor that can potentially be a scalar integer, you can wrap the tensor in `I()`, or use op_shape().

```
(x <- op_convert_to_tensor(2L))

## tf.Tensor(2, shape=(), dtype=int32)

# by default, shape() treats scalar integer tensors as axis values
shape(x)

## shape(tf.Tensor(2, shape=(), dtype=int32))

# to access the shape of a scalar integer,
# call `op_shape()`, or protect with `I()`
op_shape(x)

## shape()

shape(I(x))

## shape()
```

See Also

op_shape()

split_dataset *Splits a dataset into a left half and a right half (e.g. train / test).*

Description

Splits a dataset into a left half and a right half (e.g. train / test).

Usage

```
split_dataset(
  dataset,
  left_size = NULL,
  right_size = NULL,
  shuffle = FALSE,
  seed = NULL
)
```

Arguments

dataset	A `tf$data$Dataset`, a `torch$utils$data$Dataset` object, or a list of arrays with the same length.
left_size	If float (in the range `[0, 1]`), it signifies the fraction of the data to pack in the left dataset. If integer, it signifies the number of samples to pack in the left dataset. If `NULL`, defaults to the complement to `right_size`. Defaults to `NULL`.
right_size	If float (in the range `[0, 1]`), it signifies the fraction of the data to pack in the right dataset. If integer, it signifies the number of samples to pack in the right dataset. If `NULL`, defaults to the complement to `left_size`. Defaults to `NULL`.
shuffle	Boolean, whether to shuffle the data before splitting it.
seed	A random seed for shuffling.

Value

A list of two `tf$data$Dataset` objects: the left and right splits.

Examples

```
data <- random_uniform(c(1000, 4))
c(left_ds, right_ds) %<-% split_dataset(list(data$numpy()), left_size = 0.8)
left_ds$cardinality()

## tf.Tensor(800, shape=(), dtype=int64)

right_ds$cardinality()

## tf.Tensor(200, shape=(), dtype=int64)
```

summary.keras.src.models.model.Model

Print a summary of a Keras Model

Description

Print a summary of a Keras Model

Usage

```
## S3 method for class 'keras.src.models.model.Model'
summary(object, ...)

## S3 method for class 'keras.src.models.model.Model'
format(
  x,
  line_length = min(getOption("width"), 180),
  positions = NULL,
  expand_nested = FALSE,
  show_trainable = NA,
  ...,
  layer_range = NULL,
  compact = TRUE
)

## S3 method for class 'keras.src.models.model.Model'
print(x, ...)
```

Arguments

object, x	Keras model instance
...	for summary() and print(), passed on to format(). For format(), passed on to model$summary().
line_length	Total length of printed lines
positions	Relative or absolute positions of log elements in each line. If not provided, defaults to c(0.33, 0.55, 0.67, 1.0).
expand_nested	Whether to expand the nested models. If not provided, defaults to FALSE.
show_trainable	Whether to show if a layer is trainable. If not provided, defaults to FALSE.
layer_range	a list, tuple, or vector of 2 strings, which is the starting layer name and ending layer name (both inclusive) indicating the range of layers to be printed in summary. It also accepts regex patterns instead of exact name. In such case, start predicate will be the first element it matches to layer_range[[1]] and the end predicate will be the last element it matches to layer_range[[1]]. By default NULL which considers all layers of model.
compact	Whether to remove white-space only lines from the model summary. (Default TRUE)

Value

format() returns a length 1 character vector. print() returns the model object invisibly. summary() returns the output of format() invisibly after printing it.

Enabling color output in Knitr (RMarkdown, Quarto)

In order to enable color output in a quarto or rmarkdown document with an html output format (include revealjs presentations), then you will need to do the following in a setup chunk:

```
```{r setup, include = FALSE}
options(cli.num_colors = 256)
fansi::set_knit_hooks(knitr::knit_hooks)
options(width = 75) # adjust as needed for format
```
```

keras_model_sequential()
pop_layer()
set_state_tree()

`test_on_batch` *Test the model on a single batch of samples.*

Description

Test the model on a single batch of samples.

Usage

```
test_on_batch(object, x, y = NULL, sample_weight = NULL, ...)
```

Arguments

`object`	Keras model object
`x`	Input data. Must be array-like.
`y`	Target data. Must be array-like.
`sample_weight`	Optional array of the same length as x, containing weights to apply to the model's loss for each sample. In the case of temporal data, you can pass a 2D array with shape `(samples, sequence_length)`, to apply a different weight to every timestep of every sample.
`...`	for forward/backward compatability

Value

A scalar loss value (when no metrics), or a named list of loss and metric values (if there are metrics).

See Also

- https://keras.io/api/models/model_training_apis#testonbatch-method

Other model training:
compile.keras.src.models.model.Model()

train_on_batch()

---

text_dataset_from_directory

Generates a `tf.data.Dataset` *from text files in a directory.*

Description

If your directory structure is:

```
main_directory/
...class_a/
......a_text_1.txt
......a_text_2.txt
...class_b/
......b_text_1.txt
......b_text_2.txt
```

Then calling `text_dataset_from_directory(main_directory, labels='inferred')` will return a `tf.data.Dataset` that yields batches of texts from the subdirectories `class_a` and `class_b`, together with labels 0 and 1 (0 corresponding to `class_a` and 1 corresponding to `class_b`).

Only `.txt` files are supported at this time.

Usage

```
text_dataset_from_directory(
  directory,
  labels = "inferred",
  label_mode = "int",
  class_names = NULL,
  batch_size = 32L,
  max_length = NULL,
  shuffle = TRUE,
  seed = NULL,
  validation_split = NULL,
  subset = NULL,
  follow_links = FALSE,
  verbose = TRUE
)
```

Arguments

directory	Directory where the data is located. If labels is "inferred", it should contain subdirectories, each containing text files for a class. Otherwise, the directory structure is ignored.
labels	Either "inferred" (labels are generated from the directory structure), NULL (no labels), or a list/tuple of integer labels of the same size as the number of text files found in the directory. Labels should be sorted according to the alphanumeric order of the text file paths (obtained via os.walk(directory) in Python).
label_mode	String describing the encoding of labels. Options are: • "int": means that the labels are encoded as integers (e.g. for sparse_categorical_crossentropy loss). • "categorical" means that the labels are encoded as a categorical vector (e.g. for categorical_crossentropy loss). • "binary" means that the labels (there can be only 2) are encoded as float32 scalars with values 0 or 1 (e.g. for binary_crossentropy). • NULL (no labels).
class_names	Only valid if "labels" is "inferred". This is the explicit list of class names (must match names of subdirectories). Used to control the order of the classes (otherwise alphanumerical order is used).
batch_size	Size of the batches of data. If NULL, the data will not be batched (the dataset will yield individual samples). Defaults to 32.
max_length	Maximum size of a text string. Texts longer than this will be truncated to max_length.
shuffle	Whether to shuffle the data. If set to FALSE, sorts the data in alphanumeric order. Defaults to TRUE.
seed	Optional random seed for shuffling and transformations.
validation_split	Optional float between 0 and 1, fraction of data to reserve for validation.
subset	Subset of the data to return. One of "training", "validation" or "both". Only used if validation_split is set. When subset="both", the utility returns a tuple of two datasets (the training and validation datasets respectively).
follow_links	Whether to visits subdirectories pointed to by symlinks. Defaults to FALSE.
verbose	Whether to display number information on classes and number of files found. Defaults to TRUE.

Value

A tf.data.Dataset object.

- If label_mode is NULL, it yields string tensors of shape (batch_size,), containing the contents of a batch of text files.
- Otherwise, it yields a tuple (texts, labels), where texts has shape (batch_size,) and labels follows the format described below.

Rules regarding labels format:

- if `label_mode` is `int`, the labels are an `int32` tensor of shape `(batch_size,)`.
- if `label_mode` is `binary`, the labels are a `float32` tensor of 1s and 0s of shape `(batch_size, 1)`.
- if `label_mode` is `categorical`, the labels are a `float32` tensor of shape `(batch_size, num_classes)`, representing a one-hot encoding of the class index.

`timeseries_dataset_from_array` *Creates a dataset of sliding windows over a timeseries provided as array.*

Description

This function takes in a sequence of data-points gathered at equal intervals, along with time series parameters such as length of the sequences/windows, spacing between two sequence/windows, etc., to produce batches of timeseries inputs and targets.

Usage

```
timeseries_dataset_from_array(
  data,
  targets,
  sequence_length,
  sequence_stride = 1L,
  sampling_rate = 1L,
  batch_size = 128L,
  shuffle = FALSE,
  seed = NULL,
  start_index = NULL,
  end_index = NULL
)
```

Arguments

`data`	array or eager tensor containing consecutive data points (timesteps). The first dimension is expected to be the time dimension.
`targets`	Targets corresponding to timesteps in `data`. `targets[i]` should be the target corresponding to the window that starts at index `i` (see example 2 below). Pass `NULL` if you don't have target data (in this case the dataset will only yield the input data).
`sequence_length`	Length of the output sequences (in number of timesteps).
`sequence_stride`	Period between successive output sequences. For stride `s`, output samples would start at index `data[i]`, `data[i + s]`, `data[i + 2 * s]`, etc.
`sampling_rate`	Period between successive individual timesteps within sequences. For rate `r`, timesteps `data[i], data[i + r], ... data[i + sequence_length]` are used for creating a sample sequence.
`batch_size`	Number of timeseries samples in each batch (except maybe the last one). If `NULL`, the data will not be batched (the dataset will yield individual samples).
`shuffle`	Whether to shuffle output samples, or instead draw them in chronological order.

seed	Optional int; random seed for shuffling.
start_index	Optional int; data points earlier (exclusive) than start_index will not be used in the output sequences. This is useful to reserve part of the data for test or validation.
end_index	Optional int; data points later (exclusive) than end_index will not be used in the output sequences. This is useful to reserve part of the data for test or validation.

Value

A tf$data$Dataset instance. If targets was passed, the dataset yields list (batch_of_sequences, batch_of_targets). If not, the dataset yields only batch_of_sequences.

Example 1:

Consider indices [0, 1, ... 98]. With sequence_length=10, sampling_rate=2, sequence_stride=3, shuffle=FALSE, the dataset will yield batches of sequences composed of the following indices:

```
First sequence:  [0  2  4  6  8 10 12 14 16 18]
Second sequence: [3  5  7  9 11 13 15 17 19 21]
Third sequence:  [6  8 10 12 14 16 18 20 22 24]
...
Last sequence:   [78 80 82 84 86 88 90 92 94 96]
```

In this case the last 2 data points are discarded since no full sequence can be generated to include them (the next sequence would have started at index 81, and thus its last step would have gone over 98).

Example 2: Temporal regression.

Consider an array data of scalar values, of shape (steps,). To generate a dataset that uses the past 10 timesteps to predict the next timestep, you would use:

```
data <- op_array(1:20)
input_data <- data[1:10]
targets <- data[11:20]
dataset <- timeseries_dataset_from_array(
  input_data, targets, sequence_length=10)
iter <- reticulate::as_iterator(dataset)
reticulate::iter_next(iter)

## [[1]]
## tf.Tensor([[ 1  2  3  4  5  6  7  8  9 10]], shape=(1, 10), dtype=int32)
##
## [[2]]
## tf.Tensor([11], shape=(1), dtype=int32)
```

Example 3: Temporal regression for many-to-many architectures.

Consider two arrays of scalar values X and Y, both of shape (100,). The resulting dataset should consist samples with 20 timestamps each. The samples should not overlap. To generate a dataset that uses the current timestamp to predict the corresponding target timestep, you would use:

```
X <- op_array(1:100)
Y <- X*2

sample_length <- 20
input_dataset <- timeseries_dataset_from_array(
    X, NULL, sequence_length=sample_length, sequence_stride=sample_length)
target_dataset <- timeseries_dataset_from_array(
    Y, NULL, sequence_length=sample_length, sequence_stride=sample_length)

inputs <- reticulate::as_iterator(input_dataset) %>% reticulate::iter_next()
targets <- reticulate::as_iterator(target_dataset) %>% reticulate::iter_next()
```

---

to_categorical *Converts a class vector (integers) to binary class matrix.*

Description

E.g. for use with loss_categorical_crossentropy().

Usage

```
to_categorical(x, num_classes = NULL)
```

Arguments

x	Array-like with class values to be converted into a matrix (integers from 0 to num_classes - 1). R factors are coerced to integer and offset to be 0-based, i.e., as.integer(x) - 1L.
num_classes	Total number of classes. If NULL, this would be inferred as max(x) + 1. Defaults to NULL.

Value

A binary matrix representation of the input as an R array. The class axis is placed last.

Examples

```
a <- to_categorical(c(0, 1, 2, 3), num_classes=4)
print(a)

##      [,1] [,2] [,3] [,4]
## [1,]    1    0    0    0
## [2,]    0    1    0    0
## [3,]    0    0    1    0
## [4,]    0    0    0    1

b <- array(c(.9, .04, .03, .03,
             .3, .45, .15, .13,
             .04, .01, .94, .05,
             .12, .21, .5, .17),
             dim = c(4, 4))
loss <- op_categorical_crossentropy(a, b)
loss
```

```
## tf.Tensor([0.41284522 0.45601739 0.54430155 0.80437282], shape=(4), dtype=float64)
```

```
loss <- op_categorical_crossentropy(a, a)
loss
```

```
## tf.Tensor([1.00000005e-07 1.00000005e-07 1.00000005e-07 1.00000005e-07], shape=(4), dtype=float64)
```

`train_on_batch` *Runs a single gradient update on a single batch of data.*

Description

Runs a single gradient update on a single batch of data.

Usage

```
train_on_batch(object, x, y = NULL, sample_weight = NULL, class_weight = NULL)
```

Arguments

`object`	Keras model object
`x`	Input data. Must be array-like.
`y`	Target data. Must be array-like.
`sample_weight`	Optional array of the same length as x, containing weights to apply to the model's loss for each sample. In the case of temporal data, you can pass a 2D array with shape `(samples, sequence_length)`, to apply a different weight to every timestep of every sample.
`class_weight`	Optional named list mapping class indices (integers, 0-based) to a weight (float) to apply to the model's loss for the samples from this class during training. This can be useful to tell the model to "pay more attention" to samples from an under-represented class. When `class_weight` is specified and targets have a rank of 2 or greater, either `y` must be one-hot encoded, or an explicit final dimension of 1 must be included for sparse class labels.

Value

A scalar loss value (when no metrics), or a named list of loss and metric values (if there are metrics). The property `model$metrics_names` will give you the display labels for the scalar outputs.

`predict_on_batch()`
`test_on_batch()`

use_backend *Configure a Keras backend*

Description

Configure a Keras backend

Usage

```
use_backend(backend, gpu = NA)
```

Arguments

backend	string, can be "tensorflow", "jax", "numpy", or "torch".
gpu	bool, whether to use the GPU. If NA (default), it will attempt to detect GPU availability on Linux. On M-series Macs, it defaults to FALSE for TensorFlow and TRUE for JAX. On Windows, it defaults to FALSE.

Details

These functions allow configuring which backend keras will use. Note that only one backend can be configured at a time.

The function should be called after `library(keras3)` and before calling other functions within the package (see below for an example).

There is experimental support for changing the backend after keras has initialized. using `config_set_backend()`.

```
library(keras3)
use_backend("tensorflow")
```

Value

Called primarily for side effects. Returns the provided backend, invisibly.

with_custom_object_scope *Provide a scope with mappings of names to custom objects*

Description

Provide a scope with mappings of names to custom objects

Usage

```
with_custom_object_scope(objects, expr)
```

Arguments

objects	Named list of objects
expr	Expression to evaluate

Details

There are many elements of Keras models that can be customized with user objects (e.g. losses, metrics, regularizers, etc.). When loading saved models that use these functions you typically need to explicitly map names to user objects via the custom_objects parameter.

The with_custom_object_scope() function provides an alternative that lets you create a named alias for a user object that applies to an entire block of code, and is automatically recognized when loading saved models.

Value

The result from evaluating expr within the custom object scope.

Examples

```
# define custom metric
metric_top_3_categorical_accuracy <-
  custom_metric("top_3_categorical_accuracy", function(y_true, y_pred) {
    metric_top_k_categorical_accuracy(y_true, y_pred, k = 3)
  })

with_custom_object_scope(c(top_k_acc = sparse_top_k_cat_acc), {

  # ...define model...

  # compile model (refer to "top_k_acc" by name)
  model |> compile(
    loss = "binary_crossentropy",
    optimizer = optimizer_nadam(),
    metrics = c("top_k_acc")
  )

  # save the model
  model |> save_model("my_model.keras")

  # loading the model within the custom object scope doesn't
  # require explicitly providing the custom_object
  reloaded_model <- load_model("my_model.keras")
})
```

`zip_lists` *Zip lists*

Description

This is conceptually similar to `zip()` in Python, or R functions `purrr::transpose()` and `data.table::transpose()` (albeit, accepting elements in `...` instead of a single list), with one crucial difference: if the provided objects are named, then matching is done by names, not positions.

Usage

```
zip_lists(...)
```

Arguments

`...`	R lists or atomic vectors, optionally named.

Details

All arguments supplied must be of the same length. If positional matching is required, then all arguments provided must be unnamed. If matching by names, then all arguments must have the same set of names, but they can be in different orders.

Value

A inverted list
